The UPDATE statement updates columns in existing table rows with new values. The SET clause indicates which columns to modify and the values they should be given. The WHERE clause, if given, specifies which rows should be updated. Otherwise, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a limit on the number of rows that can be updated.

The UPDATE statement supports the following modifiers:

- If you use the LOW_PRIORITY keyword, execution of the UPDATE is delayed until no other clients are reading from the table.
- If you use the IGNORE keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closet valid values instead.

If you access a column from *tbl_name* in an expression, UPDATE uses the current value of the column. For example, the following statement sets the age column to one more than its current value:

```
mysql> UPDATE persondata SET age=age+1;
```

UPDATE assignments are evaluated from left to right. For example, the following statement doubles the age column, then increments it:

```
mysql> UPDATE persondata SET age=age*2, age=age+1;
```

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared NOT NULL by setting to NULL, the column is set to the default value appropriate for the data type and the warning count is incremented. The default value is 0 for numeric types, the empty string ('') for string types, and the "zero" value for date and time types.

UPDATE returns the number of rows that were actually changed. The mysql_info() C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the UPDATE.

You can use LIMIT *row_count* to restrict the scope of the UPDATE. A LIMIT clause is a rows-matched restriction. The statement stops as soon as it has found *row_count* rows that satisfy the WHERE clause, whether or not they actually were changed.

If an UPDATE statement includes an ORDER BY clause, the rows are updated in the order specified by the clause.

You can also perform UPDATE operations covering multiple tables. The *table_references* clause lists the tables involved in the join. Its syntax is described in Section 13.2.7.1, "JOIN Syntax". Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The example above shows an inner join using the comma operator, but multiple-table UPDATE statements can use any type of join allowed in SELECT statements, such as LEFT JOIN.

Note: You *cannot* use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`.

You need the `UPDATE` privilege only for columns referenced in a multiple-table `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See Section 15.2.6.4, "`FOREIGN KEY` Constraints".

Currently, you cannot update a table and select from the same table in a subquery.

13.3. MySQL Utility Statements

13.3.1. `DESCRIBE` Syntax (Get Information About Columns)

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

`DESCRIBE` provides information about the columns in a table. It is a shortcut for `SHOW COLUMNS FROM`. These statements also display information for views.

See Section 13.5.4.3, "`SHOW COLUMNS` Syntax".

`col_name` can be a column name, or a string containing the SQL '`%`' and '`_`' wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string in quotes unless it contains spaces or other special characters.

```
mysql> DESCRIBE city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
5 rows in set (0.00 sec)
```

The `Null` field indicates whether `NULL` values can be stored in the column.

The `Key` field indicates whether the column is indexed. A value of `PRI` indicates that the column is part of the table's primary key. `UNI` indicates that the column is part of a `UNIQUE` index. The `MUL` value indicates that multiple occurrences of a given value are allowed within the column.

One reason for `MUL` to be displayed on a `UNIQUE` index is that several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value. Note that in a composite index, only the leftmost column of the index has an entry in the `Key` field.

The `Default` field indicates the default value that is assigned to the column.

The `Extra` field contains any additional information that is available about a given column. In our example, the `Extra` field indicates that the `Id` column was created with the `AUTO_INCREMENT` keyword.

If the data types are different from what you expect them to be based on a `CREATE TABLE` state-

ment, note that MySQL sometimes changes data types. See Section 13.1.5.1, “Silent Column Specification Changes”.

The DESCRIBE statement is provided for compatibility with Oracle.

The SHOW CREATE TABLE and SHOW TABLE STATUS statements also provide information about tables. See Section 13.5.4, “SHOW Syntax”.

13.3.2. USE Syntax

```
USE db_name
```

The USE *db_name* statement tells MySQL to use the *db_name* database as the default (current) database for subsequent statements. The database remains the default until the end of the session or until a different USE statement is issued:

```
mysql> USE db1;
mysql> SELECT COUNT(*) FROM mytable;   # selects from db1.mytable
mysql> USE db2;
mysql> SELECT COUNT(*) FROM mytable;   # selects from db2.mytable
```

Making a particular database current by means of the USE statement does not preclude you from accessing tables in other databases. The following example accesses the author table from the db1 database and the editor table from the db2 database:

```
mysql> USE db1;
mysql> SELECT author_name,editor_name FROM author,db2.editor
    ->        WHERE author.editor_id = db2.editor.editor_id;
```

The USE statement is provided for compatibility with Sybase.

13.4. MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client connection) through statements such as SET AUTOCOMMIT, START TRANSACTION, COMMIT, and ROLLBACK. See Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”. XA transaction support allows MySQL to participate in distributed transactions as well. See Section 13.4.7, “XA Transactions”.

13.4.1. START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET AUTOCOMMIT = {0 | 1}
```

The START TRANSACTION or BEGIN statement begin a new transaction. COMMIT commits the current transaction, making its changes permanent. ROLLBACK rolls back the current transaction, canceling its changes. The SET AUTOCOMMIT statement disables or enables the default autocommit mode for the current connection.

The optional WORK keyword is supported for COMMIT and RELEASE, as are the CHAIN and RELEASE clauses. CHAIN and RELEASE can be used for additional control over transaction completion. The value of the completion_type system variable determines the default completion behavior. See Section 5.3.3, “Server System Variables”.

The AND CHAIN clause causes a new transaction to begin as soon as the current one end, and the new transaction has the same isolation level as the just-terminated transaction. The RELEASE clause causes the server to disconnect the current client connection after terminating the current transaction. Including the NO keyword suppresses CHAIN or RELEASE completion, which can be useful if the completion_type system variable is set to cause chaining or release completion by default.

By default, MySQL runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk.

If you are using a transaction-safe storage engine (like InnoDB, BDB or NDB Cluster), you can disable autocommit mode with the following statement:

```
SET AUTOCOMMIT=0;
```

After disabling autocommit mode by setting the AUTOCOMMIT variable to zero, you must use COMMIT to store your changes to disk or ROLLBACK if you want to ignore the changes you have made since the beginning of your transaction.

If you want to disable autocommit mode for a single series of statements, you can use the START TRANSACTION statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With START TRANSACTION, autocommit remains disabled until you end the transaction with COMMIT or ROLLBACK. The autocommit mode then reverts to its previous state.

BEGIN and BEGIN WORK are supported as aliases of START TRANSACTION for initiating a transaction. START TRANSACTION is standard SQL syntax and is the recommended way to start an ad-hoc transaction. The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not begin a transaction. See Section 20.2.7, “BEGIN … END Compound Statement”.

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The WITH CONSISTENT SNAPSHOT clause starts a consistent read for storage engines that are capable of it. Currently, this applies only to InnoDB. The effect is the same as issuing a START TRANSACTION followed by a SELECT from any InnoDB table. See Section 15.2.10.4, “Consistent Non-Locking Read”.

Beginning a transaction causes an implicit UNLOCK TABLES to be performed.

For best results, transactions should be performed using only tables managed by a single transactional storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as InnoDB and BDB), and the transaction isolation level is not SERIALIZABLE, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use SET TRANSACTION ISOLATION LEVEL to set the isolation level to SERIALIZABLE on a per-transaction basis as necessary.)

- If you use non-transaction-safe tables within a transaction, any changes to those tables are stored at once, regardless of the status of autocommit mode.

If you issue a ROLLBACK statement after updating a non-transactional table within a transaction, an ER_WARNING_NOT_COMPLETE_ROLLBACK warning occurs. Changes to transaction-safe tables are rolled back, but not changes to non-transaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon COMMIT. Transactions that are rolled back are not logged. (**Exception**: Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that the modifications to those tables are replicated.) See Section 5.11.3, "The Binary Log".

You can change the isolation level for transactions with SET TRANSACTION ISOLATION LEVEL. See Section 13.4.6, "SET TRANSACTION Syntax".

Rolling back can be a slow operation that may occur without the user having explicitly asked for it (for example, when an error occurs). Because of this, SHOW PROCESSLIST displays Rolling back in the State column for the connection during implicit and explicit (ROLLBACK SQL command) rollbacks.

13.4.2. Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a ROLLBACK statement.

13.4.3. Statements That Cause an Implicit Commit

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a COMMIT before executing the statement:

- ALTER FUNCTION, ALTER PROCEDURE, ALTER TABLE, BEGIN, CREATE DATABASE, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE TABLE, DROP DATABASE, DROP FUNCTION, DROP INDEX, DROP PROCEDURE, DROP TABLE, LOAD MASTER DATA, LOCK TABLES, RENAME TABLE, SET AUTOCOMMIT=1, START TRANSACTION, TRUNCATE TABLE, UNLOCK TABLES.
- UNLOCK TABLES commits a transaction only if any tables currently are locked.
- The statements CREATE TABLE, CREATE DATABASE DROP DATABASE, TRUNCATE TABLE, ALTER FUNCTION, ALTER PROCEDURE, CREATE FUNCTION, CREATE PROCEDURE, DROP FUNCTION, and DROP PROCEDURE statements cause an implicit commit.
- The CREATE TABLE statement in InnoDB is processed as a single transaction. This means that a ROLLBACK from the user does not undo CREATE TABLE statements the user made during that transaction.

Transactions cannot be nested. This is a consequence of the implicit COMMIT performed for any current transaction when you issue a START TRANSACTION statement or one of its synonyms.

13.4.4. SAVEPOINT and ROLLBACK TO SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO SAVEPOINT identifier
```

```
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements SAVEPOINT, ROLLBACK TO SAVEPOINT, RELEASE SAVEPOINT and the optional WORK keyword for ROLLBACK.

The SAVEPOINT statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The ROLLBACK TO SAVEPOINT statement rolls back a transaction to the named savepoint. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (Note that for a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1181: Got error 153 during ROLLBACK
```

The RELEASE SAVEPOINT statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a COMMIT, or a ROLLBACK that does not name a savepoint.

Beginning with MySQL 5.0.17, a new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

13.4.5. LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
    tbl_name [AS alias] {READ [LOCAL] | [LOW_PRIORITY] WRITE}
    [, tbl_name [AS alias] {READ [LOCAL] | [LOW_PRIORITY] WRITE}] ...
UNLOCK TABLES
```

LOCK TABLES locks tables for the current thread. If any of the tables are locked by other threads, it blocks until all locks can be acquired. UNLOCK TABLES releases any locks held by the current thread. All tables that are locked by the current thread are implicitly unlocked when the thread issues another LOCK TABLES, or when the connection to the server is closed.

A table lock protects only against inappropriate reads or writes by other clients. The client holding the lock, even a read lock, can perform table-level operations such as DROP TABLE.

Note the following regarding the use of LOCK TABLES with transactional tables:

- LOCK TABLES is not transaction-safe and implicitly commits any active transactions before attempting to lock the tables. Also, beginning a transaction (for example, with START TRANSACTION) implicitly performs an UNLOCK TABLES. (See Section 13.4.3, “Statements That Cause an Implicit Commit”.)

- The correct way to use LOCK TABLES with transactional tables, like InnoDB, is to set AUTOCOMMIT = 0 and not to call UNLOCK TABLES until you commit the transaction explicitly. When you call LOCK TABLES, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its table lock at the next commit, but for MySQL to release its table lock, you have to call UNLOCK TABLES. You should not have AUTOCOMMIT = 1, because then InnoDB releases its table lock immediately after the call of LOCK TABLES, and

deadlocks can very easily happen. Note that we do not acquire the InnoDB table lock at all if AUTOCOMMIT=1, in order to help old applications avoid unnecessary deadlocks.

- ROLLBACK does not release MySQL's non-transactional table locks.

To use LOCK TABLES, you must have the LOCK TABLES privilege and the SELECT privilege for the involved tables.

The main reasons to use LOCK TABLES are for emulating transactions or to get more speed when updating tables. This is explained in more detail later.

If a thread obtains a READ lock on a table, that thread (and all other threads) can only read from the table. If a thread obtains a WRITE lock on a table, only the thread holding the lock can write to the table. Other threads are blocked from doing so until the lock has been released.

The difference between READ LOCAL and READ is that READ LOCAL allows non-conflicting INSERT statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database files outside MySQL while you hold the lock. For InnoDB tables, READ LOCAL is the same as READ.

When you use LOCK TABLES, you must lock all tables that you are going to use in your queries. While the locks obtained with a LOCK TABLES statement are in effect, you cannot access any tables that were not locked by the statement. Also, you cannot use a locked table multiple times in a single query — use aliases instead, in which case you must obtain a lock for each alias separately.

```
mysql> LOCK TABLE t WRITE, t AS t1 WRITE;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

If your queries refer to a table using an alias, then you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your queries using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

WRITE locks normally have higher priority than READ locks to ensure that updates are processed as soon as possible. This means that if one thread obtains a READ lock and then another thread requests a WRITE lock, subsequent READ lock requests wait until the WRITE thread has gotten the lock and released it. You can use LOW_PRIORITY WRITE locks to allow other threads to obtain READ locks while the thread is waiting for the WRITE lock. You should use LOW_PRIORITY WRITE locks only if you are sure that eventually there will be a time when no threads have a READ lock.

LOCK TABLES works as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is locked with a read and a write lock, put the write lock before the read lock.
3. Lock one table at a time until the thread gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy:

If you are using a `LOW_PRIORITY WRITE` lock for a table, it means only that MySQL waits for this particular lock until there are no threads that want a `READ` lock. When the thread has gotten the `WRITE` lock and is waiting to get the lock for the next table in the lock table list, all other threads wait for the `WRITE` lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

You can safely use `KILL` to terminate a thread that is waiting for a table lock. See Section 13.5.5.3, "`KILL` Syntax".

Note that you should *not* lock any tables that you are using with `INSERT DELAYED` because in that case the `INSERT` is performed by a separate thread.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other thread can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them. The downside is that no thread can update a `READ`-locked table (including the one holding the lock) and no thread can access a `WRITE`-locked table other than the one holding the lock.

  The reason some `MyISAM` operations are faster under `LOCK TABLES` is that MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

- If you are using a storage engine in MySQL that does not support transactions, you must use `LOCK TABLES` if you want to ensure that no other thread comes between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

  ```
  mysql> LOCK TABLES trans READ, customer WRITE;
  mysql> SELECT SUM(value) FROM trans WHERE customer_id=some_id;
  mysql> UPDATE customer
      ->     SET total_value=sum_from_previous_statement
      ->     WHERE customer_id=some_id;
  mysql> UNLOCK TABLES;
  ```

  Without `LOCK TABLES`, it is possible that another thread might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET` *`value`*`=`*`value`*`+`*`new_value`*) or the `LAST_INSERT_ID()` function, See Section 1.9.5.3, "Transactions and Atomic Operations".

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See Section 12.9.4, "Miscellaneous Functions".

See Section 7.3.1, "Locking Methods", for more information on locking policy.

You can lock all tables in all databases with read locks with the `FLUSH TABLES WITH READ LOCK` statement. See Section 13.5.5.2, "`FLUSH` Syntax". This is a very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

Note: If you use `ALTER TABLE` on a locked table, it may become unlocked. See Section A.7.1, "Problems with `ALTER TABLE`".

13.4.6. SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL
{ READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE }
```

This statement sets the transaction isolation level for the next transaction, globally, or for the current session.

The default behavior of `SET TRANSACTION` is to set the isolation level for the next (not yet started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on. Existing connections are unaffected. You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

For descriptions of each `InnoDB` transaction isolation level, see Section 15.2.10.3, "`InnoDB` and `TRANSACTION ISOLATION LEVEL`". `InnoDB` supports each of these levels in MySQL 5.1. The default level is `REPEATABLE READ`.

You can set the initial default global isolation level for `mysqld` with the `--transaction-isolation` option. See Section 5.3.1, "`mysqld` Command-Line Options".

13.4.7. XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at http://www.opengroup.org/public/pubs/catalog/c193.htm. Limitations of the current XA implementation are described in Section I.5, "Restrictions on XA Transactions".

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Currently, among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (that is, through a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions, that is, the ability to allow multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties "up a level" so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (However, for a distributed transaction, you mus use the `SERIALIZABLE` isolation level to achieve ACID properties. It is enough to use `REPEATABLE READ` for a non-distributed transaction, but not for a distributed transaction.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as "transactional email."
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money via auto-

mated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL allows a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it's necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components musts roll back. To manage a global transaction, it's necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, When a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.4.7.1. XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid
```

```
XA RECOVER
```

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is not supported.

Each XA statement begins with the `XA` keyword, and most of them require an *`xid`* value. An *`xid`* is an XA transaction identifier. It indicates which transaction the statement applies to. *`xid`* values are supplied by the client, or generated by the MySQL server. An *`xid`* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

`gtrid` is a global transaction identifier, *`bqual`* is a branch qualifier, and *`formatID`* is a number that identifies the format used by the *`gtrid`* and *`bqual`* values. As indicated by the syntax, *`bqual`* and *`formatID`* are optional. The default *`bqual`* value is `''` if not given. The default *`formatID`* value is 1 if not given.

`gtrid` and *`bqual`* must be string literals, each up to 64 bytes (not characters) long. *`gtrid`* and *`bqual`* can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`0x6162`, `X'ab'`), or bit-value (`b'nnnn'`).

`formatID` is an unsigned integer.

The *`gtrid`* and *`bqual`* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *`gtrid`* and *`bqual`* as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *`xid`* values in a list of values returned by the `XA RECOVER` statement.

`XA START` *`xid`* starts an XA transaction with the given *`xid`* value. Each XA transaction must have a unique *`xid`* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *`gtrid`* and *`bqual`* values. All following XA statements for the XA transaction must be specified using the same *`xid`* value as that given in the `XA START` statement. If you use any of those statements but specify an *`xid`* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *`gtrid`* value in the *`xid`* value. For this reason, *`gtrid`* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *`bqual`* part of the *`xid`* value must be different for each XA transaction within a global transaction. (The requirement that *`bqual`* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See Section 13.4.7.2, “XA Transaction States”.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example *`xid`* value consisting of the parts `'abc'`, `'def'`, and 7):

```
mysql> XA RECOVER;
+----------+--------------+--------------+--------+
| formatID | gtrid_length | bqual_length | data   |
+----------+--------------+--------------+--------+
|        7 |            3 |            3 | abcdef |
+----------+--------------+--------------+--------+
```

The output columns have the following meanings:

- `formatID` is the *`formatID`* part of the transaction *`xid`*
- `gtrid_length` is the length in bytes of the *`gtrid`* part of the *`xid`*
- `bqual_length` is the length in bytes of the *`bqual`* part of the *`xid`*
- `data` is the concatenation of the *`gtrid`* and *`bqual`* parts of the *`xid`*

13.4.7.2. XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
   - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's *`xid`* value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
   - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The *`xid`* value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with START TRANSACTION, no XA statements can be used until the transaction has been committed or rolled back.

13.5. Database Administration Statements

13.5.1. Account Management Statements

13.5.1.1. CREATE USER Syntax

```
CREATE USER user [IDENTIFIED BY [PASSWORD] 'password']
    [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
```

The CREATE USER creates new MySQL accounts. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database. For each account, CREATE USER creates a new record in the mysql.user table that has no privileges. An error occurs if the account already exists.

The account can be given a password with the optional IDENTIFIED BY clause. The *user* value and the password are given the same way as for the GRANT statement. In particular, to specify the password in plain text, omit the PASSWORD keyword. To specify the password as the hashed value as returned by the PASSWORD() function, include the keyword PASSWORD. See Section 13.5.1.3, "GRANT and REVOKE Syntax".

13.5.1.2. DROP USER Syntax

```
DROP USER user [, user] ...
```

The DROP USER statement deletes one or more MySQL accounts. To use it, you must have the global CREATE USER privilege or the DELETE privilege for the mysql database. Each account is named using the same format as for GRANT or REVOKE; for example, 'jeffrey'@'localhost'. The user and host parts of the account name correspond to the User and Host column values of the user table record for the account.

With DROP USER, you can remove an account and its privileges as follows:

```
DROP USER user;
```

The statement removes privilege records for the account from all grant tables.

Important: DROP USER does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the command does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design*.

13.5.1.3. GRANT and REVOKE Syntax

```
GRANT priv_type [(column_list)] [, priv_type [(column_list)]] ...
    ON [object_type] {tbl_name | * | *.* | db_name.*}
    TO user [IDENTIFIED BY [PASSWORD] 'password']
        [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
    [REQUIRE
        NONE |
        [{SSL| X509}]
        [CIPHER 'cipher' [AND]]
        [ISSUER 'issuer' [AND]]
        [SUBJECT 'subject']]
    [WITH with_option [with_option] ...]

object_type =
    TABLE
  | FUNCTION
  | PROCEDURE

with_option =
    GRANT OPTION
  | MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
```

```
REVOKE priv_type [(column_list)] [, priv_type [(column_list)]] ...
    ON [object_type] {tbl_name | * | *.* | db_name.*}
    FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

The GRANT and REVOKE statements allow system administrators to create MySQL user accounts and to grant rights to and revoke them from accounts.

MySQL account information is stored in the tables of the mysql database. This database and the access control system are discussed extensively in Chapter 5, *Database Administration*, which you should consult for additional details.

If the grant tables hold privilege records that contain mixed-case database or table names and the lower_case_table_names system variable is set, REVOKE cannot be used to revoke the privileges. It will be necessary to manipulate the grant tables directly. (GRANT will not create such records when lower_case_table_names is set, but such records might have been created prior to setting the variable.)

Privileges can be granted at several levels:

- **Global level**

  Global privileges apply to all databases on a given server. These privileges are stored in the mysql.user table. GRANT ALL ON *.* and REVOKE ALL ON *.* grant and revoke only global privileges.

- **Database level**

  Database privileges apply to all objects in a given database. These privileges are stored in the mysql.db and mysql.host tables. GRANT ALL ON *db_name*.* and REVOKE ALL ON *db_name*.* grant and revoke only database privileges.

- **Table level**

  Table privileges apply to all columns in a given table. These privileges are stored in the mysql.tables_priv table. GRANT ALL ON *db_name.tbl_name* and REVOKE ALL ON *db_name.tbl_name* grant and revoke only table privileges.

- **Column level**

  Column privileges apply to single columns in a given table. These privileges are stored in the mysql.columns_priv table. When using REVOKE, you must specify the same columns that were granted.

- **Routine level**

  The CREATE ROUTINE, ALTER ROUTINE, EXECUTE, and GRANT privileges apply to stored routines. They can be granted at the global and database levels. Also, except for CREATE ROUTINE, these privileges can be granted at the routine level for individual routines and are stored in the mysql.procs_priv table.

The *object_type* clause should be specified as TABLE, FUNCTION, or PROCEDURE when the following object is a table, a stored function, or a stored procedure. To use this clause when upgrading from older versions of MySQL, you must upgrade your grant tables. See Section 2.10.2, “Upgrading the Grant Tables”.

To use GRANT or REVOKE, you must have the GRANT OPTION privilege, and you must have the privileges that you are granting or revoking.

To revoke all privileges, use the following syntax, which drops all global, database-, table-, and

column-level privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this REVOKE syntax, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database.

For the GRANT and REVOKE statements, priv_type can be specified as any of the following:

Privilege	Meaning
ALL [PRIVILEGES]	Sets all simple privileges except GRANT OPTION
ALTER	Allows use of ALTER TABLE
ALTER ROUTINE	Alter or drop stored routines
CREATE	Allows use of CREATE TABLE
CREATE ROUTINE	Create stored routines
CREATE TEMPORARY TABLES	Allows use of CREATE TEMPORARY TABLE
CREATE USER	Allows use of CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES.
CREATE VIEW	Allows use of CREATE VIEW
DELETE	Allows use of DELETE
DROP	Allows use of DROP TABLE
EXECUTE	Allows the user to run stored routines
FILE	Allows use of SELECT ... INTO OUTFILE and LOAD DATA INFILE
INDEX	Allows use of CREATE INDEX and DROP INDEX
INSERT	Allows use of INSERT
LOCK TABLES	Allows use of LOCK TABLES on tables for which you have the SELECT privilege
PROCESS	Allows use of SHOW FULL PROCESSLIST
REFERENCES	Not implemented
RELOAD	Allows use of FLUSH
REPLICATION CLIENT	Allows the user to ask where slave or master servers are
REPLICATION SLAVE	Needed for replication slaves (to read binary log events from the master)
SELECT	Allows use of SELECT
SHOW DATABASES	SHOW DATABASES shows all databases
SHOW VIEW	Allows use of SHOW CREATE VIEW
SHUTDOWN	Allows use of mysqladmin shutdown
SUPER	Allows use of CHANGE MASTER, KILL, PURGE MASTER LOGS, and SET GLOBAL statements, the mysqladmin debug command; allows you to connect (once) even if max_connections is reached
UPDATE	Allows use of UPDATE
USAGE	Synonym for “no privileges”
GRANT OPTION	Allows privileges to be granted

To use the EXECUTE, CREATE VIEW, SHOW VIEW, CREATE USER, CREATE ROUTINE, and ALTER ROUTINE privileges when upgrading from an earlier version of MySQL that does not have

them, you must first upgrade your grant tables as described in Section 2.10.2, “Upgrading the Grant Tables”.

The `REFERENCES` privilege currently is unused.

`USAGE` can be specified when you want to create a user that has no privileges.

Use `SHOW GRANTS` to determine what privileges the account has. See Section 13.5.4.10, “`SHOW GRANTS` Syntax”.

You can assign global privileges by using `ON *.*` syntax or database-level privileges by using `ON` *`db_name`*`.*` syntax. If you specify `ON *` and you have selected a default database, the privileges are granted in that database. (**Warning:** If you specify `ON *` and you have *not* selected a default database, the privileges granted are global.)

The `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` privileges are administrative privileges that can only be granted globally (using `ON *.*` syntax).

Other privileges can be granted globally or at more specific levels.

The only `priv_type` values you can specify for a table are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `CREATE`, `DROP`, `GRANT OPTION`, `INDEX`, and `ALTER`.

The only `priv_type` values you can specify for a column (that is, when you use a `column_list` clause) are `SELECT`, `INSERT`, and `UPDATE`.

The only `priv_type` values you can specify at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have this privilege to be able to create a routine in the first place.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, if you use `GRANT ALL ON` *`db_name`*`.*`, that is a database-level statement, so none of the global-only privileges such as `FILE` are granted.

MySQL allows you to grant privileges even on database objects that do not exist. In such cases, the privileges to be granted must include the `CREATE` privilege. *This behavior is by design*, and is intended to allow the database administrator to prepare user accounts and privileges for database objects that are to be created at a later time.

Important: *MySQL does not automatically revoke any privileges when you drop a table or database*. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Note: the ‘_’ and ‘%’ wildcards are allowed when specifying database names in `GRANT` statements that grant privileges at the global or database levels. This means, for example, that if you want to use a ‘_’ character as part of a database name, you should specify it as ‘`\_`’ in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON \`foo_bar\`.* TO ...`.

In order to accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *`user`* value in the form *`user_name`*`@`*`host_name`*. If a *`user_name`* or *`host_name`* value is legal as an unquoted identifier, you need not quote it. However, quotes are necessary to specify a *`user_name`* string containing special characters (such as ‘`-`’), or a *`host_name`* string containing special characters or wildcard characters (such as ‘`%`’); for example, `'test-user'@'test-hostname'`. Quote the username and hostname separately.

You can specify wildcards in the hostname. For example, *`user_name`*`@'%.loc.gov'` applies to *`user_name`* for any host in the `loc.gov` domain, and *`user_name`*`@'144.155.166.%'` applies to *`user_name`* for any host in the `144.155.166` class C subnet.

The simple form *`user_name`* is a synonym for *`user_name`*`@'%'`.

MySQL does not support wildcards in usernames. Anonymous users are defined by inserting entries

with `User=''` into the `mysql.user` table or by creating a user with an empty name with the `GRANT` statement:

```
mysql> GRANT ALL ON test.* TO ''@'localhost' ...
```

When specifying quoted values, quote database, table, column, and routine names as identifiers, using backticks (‘``’). Quote hostnames, usernames, and passwords as strings, using single quotes (‘''’).

Warning: If you allow anonymous users to connect to the MySQL server, you should also grant privileges to all local users as *`user_name`*`@localhost`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine.

You can determine whether this applies to you by executing the following query, which lists any anonymous users:

```
mysql> SELECT Host, User FROM mysql.user WHERE User='';
```

If you want to delete the local anonymous user account to avoid the problem just described, use these statements:

```
mysql> DELETE FROM mysql.user WHERE Host='localhost' AND User='';
mysql> FLUSH PRIVILEGES;
```

`GRANT` supports hostnames up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. Usernames can be up to 16 characters. **Note**: *The allowable length for usernames cannot be changed by altering the `mysql.user` table, and attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server*. You should never attempt to alter the grant tables in any way except by means of the `mysql_fix_privilege_tables` script as supplied by MySQL AB for use in upgrading the MySQL server.

The privileges for a table or column are formed additively as the logical `OR` of the privileges at each of the four privilege levels. For example, if the `mysql.user` table specifies that a user has a global `SELECT` privilege, the privilege cannot be denied by an entry at the database, table, or column level.

The privileges for a column can be calculated as follows:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
```

In most cases, you grant rights to a user at only one of the privilege levels, so life is not normally this complicated. The details of the privilege-checking procedure are presented in Section 5.7, “The MySQL Access Privilege System”.

If you grant privileges for a username/hostname combination that does not exist in the `mysql.user` table, an entry is added and remains there until deleted with a `DELETE` statement. In other words, `GRANT` may create `user` table entries, but `REVOKE` does not remove them; you must do that explicitly using `DROP USER` or `DELETE`.

If a new user is created or if you have global grant privileges, the user's password is set to the password specified by the `IDENTIFIED BY` clause, if one is given. If the user already had a password, this is replaced by the new one.

Warning: If you create a new user but do not specify an `IDENTIFIED BY` clause, the user has no password. This is very insecure. However, you can enable the `NO_AUTO_CREATE_USER` SQL mode to keep `GRANT` from creating a new user if it would otherwise do so, unless `IDENTIFIED BY` is given to provide the new user a non-empty password.

Passwords can also be set with the SET PASSWORD statement. See Section 13.5.1.5, "SET PASSWORD Syntax".

In the IDENTIFIED BY clause, the password should be given as the literal password value. It is unnecessary to use the PASSWORD() function as it is for the SET PASSWORD statement. For example:

```
GRANT ... IDENTIFIED BY 'mypass';
```

If you do not want to send the password in clear text and you know the hashed value that PASSWORD() would return for the password, you can specify the hashed value preceded by the keyword PASSWORD:

```
GRANT ...
IDENTIFIED BY PASSWORD '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

In a C program, you can get the hashed value by using the make_scrambled_password() C API function.

If you grant privileges for a database, an entry in the mysql.db table is created if needed. If all privileges for the database are removed with REVOKE, this entry is deleted.

If a user has no privileges for a table, the table name is not displayed when the user requests a list of tables (for example, with a SHOW TABLES statement).

The SHOW DATABASES privilege allows the account to see database names by issuing the SHOW DATABASE statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the --skip-show-database option.

The WITH GRANT OPTION clause gives the user the ability to give to other users any privileges the user has at the specified privilege level. You should be careful to whom you give the GRANT OPTION privilege, because two users with different privileges may be able to join privileges!

You cannot grant another user a privilege which you yourself do not have; the GRANT OPTION privilege allows you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the GRANT OPTION privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user. Suppose that you grant a user the INSERT privilege on a database. If you then grant the SELECT privilege on the database and specify WITH GRANT OPTION, that user can give to other users not only the SELECT privilege, but also INSERT. If you then grant the UPDATE privilege to the user on the database, the user can grant INSERT, SELECT, and UPDATE.

You should not grant ALTER privileges to a normal user. If you do that, the user can try to subvert the privilege system by renaming tables!

The MAX_QUERIES_PER_HOUR *count*, MAX_UPDATES_PER_HOUR *count*, and MAX_CONNECTIONS_PER_HOUR *count* options limit the number of queries, updates, and logins a user can perform during any given one-hour period. If *count* is 0 (the default), this means that there is no limitation for that user.

The MAX_USER_CONNECTIONS *count* option limits the maximum number of simultaneous connections that the account can make. If *count* is 0 (the default), the max_user_connections system variable determines the number of simultaneous connections for the account.

Note: To specify any of these resource-limit options for an existing user without affecting existing privileges, use GRANT USAGE ON *.* ... WITH MAX_....

See Section 5.8.4, "Limiting Account Resources".

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the username and password. To specify SSL-related options for a MySQL account, use the `REQUIRE` clause of the `GRANT` statement. (For background information on the use of SSL with MySQL, see Section 5.8.7, “Using Secure Connections”.)

There are a number of different possibilities for limiting connection types for a given account:

- If the account has no SSL or X509 requirements, unencrypted connections are allowed if the username and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

- The `REQUIRE SSL` option tells the server to allow only SSL-encrypted connections for the account. Note that this option can be omitted if there are any access-control records that allow non-SSL connections.

  ```
  mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
      -> IDENTIFIED BY 'goodsecret' REQUIRE SSL;
  ```

- `REQUIRE X509` means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

  ```
  mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
      -> IDENTIFIED BY 'goodsecret' REQUIRE X509;
  ```

- `REQUIRE ISSUER '`*`issuer`*`'` places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA '*`issuer`*'. If the client presents the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```
  mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
      -> IDENTIFIED BY 'goodsecret'
      -> REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
         O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com';
  ```

  Note that the `ISSUER` value should be entered as a single string.

- `REQUIRE SUBJECT '`*`subject`*`'` places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject *`subject`*. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

  ```
  mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
      -> IDENTIFIED BY 'goodsecret'
      -> REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
         O=MySQL demo client certificate/
         CN=Tonu Samuel/Email=tonu@example.com';
  ```

  Note that the `SUBJECT` value should be entered as a single string.

- `REQUIRE CIPHER '`*`cipher`*`'` is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used. Using this option, you can ask that a specific cipher method is used to allow a connection.

  ```
  mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
      -> IDENTIFIED BY 'goodsecret'
      -> REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
  ```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause like this:

```
mysql> GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    -> IDENTIFIED BY 'goodsecret'
    -> REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
       O=MySQL demo client certificate/
       CN=Tonu Samuel/Email=tonu@example.com'
    -> AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
       O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com'
    -> AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

Note that the `SUBJECT` and `ISSUER` values each should be entered as a single string.

The `AND` keyword is optional between `REQUIRE` options.

The order of the options does not matter, but no option can be specified twice.

When `mysqld` starts, all privileges are read into memory. For details, see Section 5.7.7, “When Privilege Changes Take Effect”.

Note that if you are using table or column privileges for even one user, the server examines table and column privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

The biggest differences between the standard SQL and MySQL versions of `GRANT` are:

- In MySQL, privileges are associated with the combination of a hostname and username and not with only a username.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `TRIGGER` or `UNDER` privileges.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See Section 13.5.1.2, “`DROP USER` Syntax”.
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit `REVOKE` statements or by manipulating values stored in the MySQL grant tables.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you omit those columns for which you do not have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. Section 5.3.2, “The Server SQL Mode”, discusses strict mode. Section 13.1.5, “`CREATE TABLE` Syntax”, discusses implicit default values.

  The columns for which you don't have the `INSERT` privilege are set to their default values. Standard SQL requires you to have the `INSERT` privilege on all columns.

  In MySQL, if you have the INSERT privilege on only some of the columns in a table, you can still execute INSERT statements on the table — provided you omit the columns on which you do not have the privilege from your INSERT statement; those columns will be set to their default values. Under strict mode (i.e. when sql_mode='traditional', if any of the omitted columns have no default value, the INSERT statement will be rejected.

13.5.1.4. RENAME USER Syntax

```
RENAME USER old_user TO new_user
```

```
    [, old_user TO new_user] ...
```

The RENAME USER statement renames existing MySQL accounts. To use it, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database. An error occurs if any old account does not exist or any new account exists. The *old_user* and *new_user* values are given the same way as for the GRANT statement.

13.5.1.5. SET PASSWORD Syntax

```
SET PASSWORD = PASSWORD('some password')
SET PASSWORD FOR user = PASSWORD('some password')
```

The SET PASSWORD statement assigns a password to an existing MySQL user account.

The first syntax sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

The second syntax sets the password for a specific account on the current server host. Only clients with the UPDATE privilege for the mysql database can do this. The *user* value should be given in *user_name*@*host_name* format, where *user_name* and *host_name* are exactly as they are listed in the User and Host columns of the mysql.user table entry. For example, if you had an entry with User and Host column values of 'bob' and '%.loc.gov', you would write the statement like this:

```
mysql> SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

That is equivalent to the following statements:

```
mysql> UPDATE mysql.user SET Password=PASSWORD('newpass')
    -> WHERE User='bob' AND Host='%.loc.gov';
mysql> FLUSH PRIVILEGES;
```

Note: If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not use the preceding SET PASSWORD or UPDATE statement without reading Section 5.7.9, “Password Hashing in MySQL 4.1”, first. The password format changed in MySQL 4.1, and under certain circumstances it is possible that if you change your password, you might not be able to connect to the server afterward.

You can see what your current authentication user@host entry is by executing SELECT CURRENT_USER().

13.5.2. Table Maintenance Statements

13.5.2.1. ANALYZE TABLE Syntax

```
ANALYZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

This statement analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock. This works with MyISAM, BDB, and InnoDB tables. For MyISAM tables, this statement is equivalent to using myisamchk -a.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant.

The statement returns a table with the following columns:

Column	Value
Table	The table name

Op	Always analyze
Msg_type	One of status, error, info, or warning
Msg_text	The message

You can check the stored key distribution with the SHOW INDEX statement. See Section 13.5.4.11, "SHOW INDEX Syntax".

If the table has not changed since the last ANALYZE TABLE statement, the table is not analyzed again.

ANALYZE TABLE statements are written to the binary log unless the optional NO_WRITE_TO_BINLOG keyword (or its alias LOCAL) is used.

13.5.2.2. BACKUP TABLE Syntax

```
BACKUP TABLE tbl_name [, tbl_name] ... TO '/path/to/backup/directory'
```

Note: This statement is deprecated. We are working on a better replacement for it that will provide online backup capabilities. In the meantime, the mysqlhotcopy script can be used instead.

BACKUP TABLE copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for MyISAM tables. It copies the .frm definition and .MYD data files. The .MYI index file can be rebuilt from those two files. The directory should be specified as a full pathname.

Before using this statement, please see Section 5.9.1, "Database Backups".

During the backup, a read lock is held for each table, one at time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), you must first issue a LOCK TABLES statement to obtain a read lock for every table in the group.

The statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always backup
Msg_type	One of status, error, info, or warning
Msg_text	The message

13.5.2.3. CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option = {QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

Checks a table or tables for errors. CHECK TABLE works for MyISAM and InnoDB tables. For MyISAM tables, the key statistics are updated.

CHECK TABLE can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

The CHECK TABLE statement returns a table with the following columns:

Column	Value
Table	The table name

Op	Always check
Msg_type	One of status, error, info, or warning
Msg_text	The message

Note that the statement might produce many rows of information for each checked table. The last row has a Msg_type value of status and the Msg_text normally should be OK. If you don't get OK, or Table is already up to date you should normally run a repair of the table. See Section 5.9.4, “Table Maintenance and Crash Recovery”. Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

The different check options that can be given are shown in the following table. These options apply only to checking MyISAM tables and are ignored for InnoDB tables and views.

Type	Meaning
QUICK	Do not scan the rows to check for incorrect links.
FAST	Check only tables that have not been closed properly.
CHANGED	Check only tables that have been changed since the last check or that have not been closed properly.
MEDIUM	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys.
EXTENDED	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time.

If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check *tbl_name* on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

You can combine check options, as in the following example, which does a quick check on the table to see whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note: In some cases, CHECK TABLE changes the table. This happens if the table is marked as “corrupted” or “not closed properly” but CHECK TABLE does not find any problems in the table. In this case, CHECK TABLE marks the table as okay.

If a table is corrupted, it is most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

FAST and CHANGED are mostly intended to be used from a script (for example, to be executed from cron) if you want to check tables from time to time. In most cases, FAST is to be preferred over CHANGED. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

EXTENDED is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. (This is very unlikely if a normal check has succeeded.)

Some problems reported by CHECK TABLE cannot be corrected automatically:

- `Found row where the auto_increment column has the value 0`.

  This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, simply execute an `UPDATE` statement to set the column to some value other than 0.

13.5.2.4. `CHECKSUM TABLE` Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

Reports a table checksum.

If `QUICK` is specified, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option, currently supported only for `MyISAM` tables. See Section 13.1.5, “`CREATE TABLE` Syntax”.

In `EXTENDED` mode the whole table is read row by row and the checksum is calculated. This can be very slow for large tables.

By default, if neither `QUICK` nor `EXTENDED` is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

`CHECKSUM TABLE` returns `NULL` for non-existent tables. A warning is generated for this condition.

13.5.2.5. `OPTIMIZE TABLE` Syntax

```
OPTIMIZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have `VARCHAR`, `BLOB`, or `TEXT` columns). Deleted records are maintained in a linked list and subsequent `INSERT` operations reuse old record positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file.

In most setups, you need not run `OPTIMIZE TABLE` at all. Even if you do a lot of updates to variable-length rows, it is not likely that you need to do this more than once a week or month and only on certain tables.

`OPTIMIZE TABLE` works only on `MyISAM`, `BDB`, and `InnoDB` tables.

For `MyISAM` tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

For BDB tables, OPTIMIZE TABLE currently is mapped to ANALYZE TABLE. For InnoDB tables, it is mapped to ALTER TABLE, which rebuilds the table. Rebuilding updates index statistics and frees unused space in the clustered index. See Section 13.5.2.1, "ANALYZE TABLE Syntax".

You can make OPTIMIZE TABLE work on other storage engines by starting mysqld with the --skip-new or --safe-mode option; in this case, OPTIMIZE TABLE is just mapped to ALTER TABLE.

Note that MySQL locks the table during the time OPTIMIZE TABLE is running.

OPTIMIZE TABLE statements are written to the binary log unless the optional NO_WRITE_TO_BINLOG keyword(or its alias LOCAL) is used. This has been done so that OPTIMIZE TABLE commands used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

13.5.2.6. REPAIR TABLE Syntax

```
REPAIR [LOCAL | NO_WRITE_TO_BINLOG] TABLE
    tbl_name [, tbl_name] ... [QUICK] [EXTENDED] [USE_FRM]
```

REPAIR TABLE repairs a possibly corrupted table. By default, it has the same effect as myisamchk --recover *tbl_name*. REPAIR TABLE works on MyISAM and on ARCHIVE tables. See Section 15.1, "The MyISAM Storage Engine", Section 15.8, "The ARCHIVE Storage Engine".

Normally you should never have to run this statement. However, if disaster strikes, REPAIR TABLE is very likely to get back all your data from a MyISAM table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use REPAIR TABLE. See Section A.4.2, "What to Do If MySQL Keeps Crashing", and Section 15.1.4, "MyISAM Table Problems".

This statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always repair
Msg_type	One of status, error, info, or warning
Msg_text	The message

The REPAIR TABLE statement might produce many rows of information for each repaired table. The last row has a Msg_type value of status and Msg_test normally should be OK. If you do not get OK, you should try repairing the table with myisamchk --safe-recover, because REPAIR TABLE does not yet implement all the options of myisamchk. We plan to make it more flexible in the future.

If QUICK is given, REPAIR TABLE tries to repair only the index tree. This type of repair is like that done by myisamchk --recover --quick.

If you use EXTENDED, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by myisamchk --safe-recover.

There is also a USE_FRM mode available for REPAIR TABLE. Use this if the .MYI index file is missing or if its header is corrupted. In this mode, MySQL re-creates the .MYI file using information from the .frm file. This kind of repair cannot be done with myisamchk. **Note**: Use this mode **only** if you cannot use regular REPAIR modes. .MYI header contains important table metadata (in particular, current AUTO_INCREMENT value and Delete link) that are lost in REPAIR ... USE_FRM. Don't use USE_FRM if the table is compressed, as this information is also stored in the .MYI file.

REPAIR TABLE statements are written to the binary log unless the optional

NO_WRITE_TO_BINLOG keyword (or its alias LOCAL) is used.

Warning: If the server dies during a REPAIR TABLE operation, it is essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. (It is always a good idea to start by making a backup.) In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario.

13.5.2.7. RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

Restores the table or tables from a backup that was made with BACKUP TABLE. Existing tables are not overwritten; if you try to restore over an existing table, you get an error. Just as BACKUP TABLE, RESTORE TABLE currently works only for MyISAM tables. The directory should be specified as a full pathname.

The backup for each table consists of its .frm format file and .MYD data file. The restore operation restores those files, then uses them to rebuild the .MYI index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

The statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always restore
Msg_type	One of status, error, info, or warning
Msg_text	The message

13.5.3. SET Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
      user_var_name = expr
    | [GLOBAL | SESSION] system_var_name = expr
    | @@[global. | session.]system_var_name = expr
```

SET sets different types of variables that affect the operation of the server or your client. It can be used to assign values to user variables or system variables.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 23.2, “Extensions to SHOW Statements”.

The SET PASSWORD statement for assigning account passwords is described in See Section 13.5.1.5, “SET PASSWORD Syntax”.

Most system variables can be changed at runtime. The system variables that can be set dynamically are described in Section 5.3.3.1, “Dynamic System Variables”.

Note: Older versions of MySQL employed SET OPTION for this command, but this usage is now deprecated in favor of SET.

The following example show the different syntaxes you can use to set variables.

A user variable is written as *@var_name* and can be set as follows:

```
SET @var_name = expr;
```

Further information about user variables is given in Section 9.3, “User Variables”.

System variables can be referred to in SET statements as *var_name*. The name optionally can be preceded by GLOBAL or @@global. to indicate explicitly that the variable is a global variable, or by SESSION, @@session., or @@ to indicate that it is a session variable. LOCAL and @@local. are synonyms for SESSION and @@session.. If no modifier is present, SET sets the session variable.

The *@@var_name* syntax for system variables is supported to make MySQL syntax compatible with some other database systems.

If you set several system variables in the same statement, the last used GLOBAL or SESSION option is used for variables that have no mode specified.

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

If you set a system variable using SESSION (the default), the value remains in effect until the current session ends or until you set the variable to a different value. If you set a system variable using GLOBAL, which requires the SUPER privilege, the value is remembered and used for new connections until the server restarts. If you want to make a variable setting permanent, you should put it in an option file. See Section 4.3.2, “Using Option Files”.

To prevent incorrect usage, MySQL produces an error if you use SET GLOBAL with a variable that can only be used with SET SESSION or if you do not specify GLOBAL (or @@) when setting a global variable.

If you want to set a SESSION variable to the GLOBAL value or a GLOBAL value to the compiled-in MySQL default value, use the DEFAULT keyword. For example, the following two statements are identical in setting the session value of max_join_size to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

You can get a list of most system variables with SHOW VARIABLES. (See Section 13.5.4.21, “SHOW VARIABLES Syntax”.) To obtain a specific variable name or list of names that match a pattern, use a LIKE clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW GLOBAL VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the wildcard character ‘%’:

```
SHOW VARIABLES LIKE 'have%';
SHOW GLOBAL VARIABLES LIKE 'have%';
```

The wildcard character can be used in any position within the pattern to be matched.

You can also get the value for a specific value by using the @@[global.|local.]var_name syntax with SELECT:

```
SELECT @@max_join_size, @@global.max_join_size;
```

When you retrieve a variable with SELECT @@var_name (that is, you do not specify global., session., or local.), MySQL returns the SESSION value if it exists and the GLOBAL value otherwise.

The following list describes variables that have non-standard syntax or that are not described in the list of system variables that is found in Section 5.3.3, “Server System Variables”. Although these variables are not displayed by `SHOW VARIABLES`, you can obtain their values with `SELECT` (with the exception of `CHARACTER SET` and `SET NAMES`). For example:

```
mysql> SELECT @@AUTOCOMMIT;
+--------------+
| @@AUTOCOMMIT |
+--------------+
|            1 |
+--------------+
```

- `AUTOCOMMIT = {0 | 1}`

  Set the autocommit mode. If set to `1`, all changes to a table take effect immediately. If set to `0`, you have to use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If you change `AUTOCOMMIT` mode from `0` to `1`, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.4.1, “`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax”.

- `BIG_TABLES = {0 | 1}`

  If set to `1`, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table` *`tbl_name`* `is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is `0` (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required. (**Note**: This variable was formerly named `SQL_BIG_TABLES`.)

- `CHARACTER SET {`*`charset_name`* `| DEFAULT}`

  This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`.

  The default mapping can be restored by using the value `DEFAULT`.

  Note that the syntax for `SET CHARACTER SET` differs from that for setting most other options.

- `FOREIGN_KEY_CHECKS = {0 | 1}`

  If set to `1` (the default), foreign key constraints for `InnoDB` tables are checked. If set to `0`, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different than that required by their parent/child relationships. See Section 15.2.6.4, “`FOREIGN KEY` Constraints”.

- `IDENTITY =` *`value`*

  The variable is a synonym for the `LAST_INSERT_ID` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@IDENTITY`, and set it using `SET IDENTITY`.

- `INSERT_ID =` *`value`*

  Set the value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `LAST_INSERT_ID =` *`value`*

Set the value to be returned from LAST_INSERT_ID(). This is stored in the binary log when you use LAST_INSERT_ID() in a statement that updates a table. Setting this variable does not update the value returned by the mysql_insert_id() C API function.

- NAMES {'*charset_name*' | DEFAULT}

  SET NAMES sets the three session system variables character_set_client, character_set_connection, and character_set_results to the given character set. Setting character_set_connection to charset_name also sets collation_connection to the default collation for charset_name.

  The default mapping can be restored by using a value of DEFAULT.

  Note that the syntax for SET NAMES differs from that for setting most other options.

- ONE_SHOT

  This is not a server system variable, but it can be used to influence the effect of variables that set the character set, the collation, and the time zone. ONE_SHOT is primarily used for replication purposes: mysqlbinlog uses SET ONE_SHOT to modify temporarily the values of character set, collation, and timezone variables to reflect at rollforward what they were originally.

  You cannot use ONE_SHOT with other than the allowed set of variables; if you try, you get an error like this:

```
mysql> SET ONE_SHOT max_allowed_packet = 1;
ERROR 1382 (HY000): The 'SET ONE_SHOT' syntax is reserved for purposes interr
```

  If ONE_SHOT is used with the allowed variables, it changes the variables as requested, but resets, after the next statement, all character set, collation, and time zone-related server system variables. The only exception when resetting doesn't happen is when the next statement is a SET statement. In other words, resetting takes place after the next non-SET statement. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;

mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;

mysql> SHOW VARIABLES LIKE '%_connection';
+--------------------------+-------------------+
| Variable_name            | Value             |
+--------------------------+-------------------+
| character_set_connection | latin5            |
| collation_connection     | latin5_turkish_ci |
+--------------------------+-------------------+

mysql> SHOW VARIABLES LIKE '%_connection';
+--------------------------+-------------------+
| Variable_name            | Value             |
+--------------------------+-------------------+
| character_set_connection | latin1            |
| collation_connection     | latin1_swedish_ci |
+--------------------------+-------------------+
```

- SQL_AUTO_IS_NULL = {0 | 1}

  If set to 1 (the default), you can find the last inserted row for a table that contains an AUTO_INCREMENT column by using the following construct:

```
WHERE auto_increment_column IS NULL
```

  This behavior is used by some ODBC programs, such as Access.

- `SQL_BIG_SELECTS = {0 | 1}`

  If set to `0`, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is `1`, which allows all `SELECT` statements.

  If you set the `max_join_size` system variable to a value other than `DEFAULT`, `SQL_BIG_SELECTS` is set to `0`.

- `SQL_BUFFER_RESULT = {0 | 1}`

  `SQL_BUFFER_RESULT` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client.

- `SQL_LOG_BIN = {0 | 1}`

  If set to `0`, no logging is done to the binary log for the client. The client must have the `SUPER` privilege to set this option.

- `SQL_LOG_OFF = {0 | 1}`

  If set to `1`, no logging is done to the general query log for this client. The client must have the `SUPER` privilege to set this option.

- `SQL_LOG_UPDATE = {0 | 1}`

  This variable is deprecated, and is mapped to `SQL_LOG_BIN`.

- `SQL_NOTES = {0 | 1}`

  When set to `1` (the default), warnings of `Note` level are recorded. When set to `0`, `Note` warnings are suppressed. `mysqldump` includes output to set this variable to `0` so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `SQL_QUOTE_SHOW_CREATE = {0 | 1}`

  If set to `1`, `SHOW CREATE TABLE` quotes table and column names. If set to `0`, quoting is disabled. This option is enabled by default so that replication works for tables with table and column names that require quoting. See Section 13.5.4.5, “`SHOW CREATE TABLE` Syntax”.

- `SQL_SAFE_UPDATES = {0 | 1}`

  If set to `1`, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows.

- `SQL_SELECT_LIMIT = {`*`value`*` | DEFAULT}`

  The maximum number of records to return from `SELECT` statements. The default value for a new connection is “unlimited.” If you have changed the limit, the default value can be restored by using a `SQL_SELECT_LIMIT` value of `DEFAULT`.

  If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `SQL_SELECT_LIMIT`.

  `SQL_SELECT_LIMIT` does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- `SQL_WARNINGS = {0 | 1}`

  This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `TIMESTAMP = {`*`timestamp_value`* `| DEFAULT}`

  Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp, not a MySQL timestamp.

- `UNIQUE_CHECKS = {0 | 1}`

  If set to `1` (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to `0`, uniqueness checks are not done for index entries inserted into `InnoDB`'s insert buffer. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

13.5.4. SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
SHOW CREATE DATABASE db_name
SHOW CREATE TABLE tbl_name
SHOW DATABASES [LIKE 'pattern']
SHOW ENGINE engine_name {LOGS | STATUS }
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW INNODB STATUS
SHOW [BDB] LOGS
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
SHOW [OPEN] TABLES [FROM db_name] [LIKE 'pattern']
SHOW TRIGGERS
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
SHOW WARNINGS [LIMIT [offset,] row_count]
```

The `SHOW` statement also has forms that provide information about replication master and slave servers and are described in Section 13.6, “Replication Statements”:

```
SHOW BINLOG EVENTS
SHOW MASTER LOGS
SHOW MASTER STATUS
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
```

If the syntax for a given `SHOW` statement includes a `LIKE '`*`pattern`*`'` part, '*`pattern`*' is a string that can contain the SQL ‘%’ and ‘_’ wildcard characters. The pattern is useful for restricting statement output to matching values.

13.5.4.1. SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET [LIKE 'pattern']
```

The `SHOW CHARACTER SET` statement shows all available character sets. It takes an optional

`LIKE` clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

The `Maxlen` column shows the maximum number of bytes used to store one character.

13.5.4.2. SHOW COLLATION Syntax

```
SHOW COLLATION [LIKE 'pattern']
```

The output from `SHOW COLLATION` includes all available character sets. It takes an optional `LIKE` clause whose *`pattern`* indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-------------------+---------+----+---------+----------+---------+
| Collation         | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         |          |       0 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       0 |
| latin1_danish_ci  | latin1  | 15 |         |          |       0 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       0 |
| latin1_general_ci | latin1  | 48 |         |          |       0 |
| latin1_general_cs | latin1  | 49 |         |          |       0 |
| latin1_spanish_ci | latin1  | 94 |         |          |       0 |
+-------------------+---------+----+---------+----------+---------+
```

The `Default` column indicates whether a collation is the default for its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

13.5.4.3. SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views.

If the data types differ from what you expect them to be based on your `CREATE TABLE` statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions for which this occurs are described in Section 13.1.5.1, “Silent Column Specification Changes”.

The `FULL` keyword causes the output to include the privileges you have as well as any per-column comments for each column.

You can use *`db_name.tbl_name`* as an alternative to the *`tbl_name`* `FROM` *`db_name`* syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. You can also list a table's columns with the `mysqlshow` *`db_name tbl_name`* command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See Section 13.3.1,

DESCRIBE Syntax (Get Information About Columns)".

13.5.4.4. SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Shows a CREATE DATABASE statement that creates the given database. SHOW CREATE SCHEMA can also be used.

```
mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
       Database: test
Create Database: CREATE DATABASE `test`
                 /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
*************************** 1. row ***************************
       Database: test
Create Database: CREATE DATABASE `test`
                 /*!40100 DEFAULT CHARACTER SET latin1 */
```

13.5.4.5. SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows a CREATE TABLE statement that creates the given table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE t (
  id INT(11) default NULL auto_increment,
  s char(60) default NULL,
  PRIMARY KEY (id)
) ENGINE=MyISAM
```

SHOW CREATE TABLE quotes table and column names according to the value of the SQL_QUOTE_SHOW_CREATE option. See Section 13.5.3, "SET Syntax".

13.5.4.6. SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS} [LIKE 'pattern']
```

SHOW DATABASES lists the databases on the MySQL server host. You can also get this list using the mysqlshow command. You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege.

If the server was started with the --skip-show-database option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

SHOW SCHEMAS can also be used.

13.5.4.7. SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {LOGS | STATUS }
```

SHOW ENGINE displays log or status information about storage engines. The following statements currently are supported:

```
SHOW ENGINE BDB LOGS
SHOW ENGINE INNODB STATUS
```

`SHOW ENGINE BDB LOGS` displays status information about existing `BDB` log files. It returns the following fields:

- `File`

  The full path to the log file.

- `Type`

  The log file type (`BDB` for Berkeley DB log files).

- `Status`

  The status of the log file (`FREE` if the file can be removed, or `IN USE` if the file is needed by the transaction subsystem)

`SHOW ENGINE INNODB STATUS` displays extensive information about the state of the `InnoDB` storage engine.

Older (and now deprecated) synonyms for these statements are `SHOW [BDB] LOGS` and `SHOW INNODB STATUS`.

`SHOW ENGINE` can be used as of MySQL 4.1.2.

13.5.4.8. `SHOW ENGINES` Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` shows you status information about the storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. `SHOW TABLE TYPES` is a deprecated synonym.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: MEMORY
     Support: YES
     Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 2. row ***************************
      Engine: MyISAM
     Support: DEFAULT
     Comment: Default engine as of MySQL 3.23 with great performance
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 3. row ***************************
      Engine: InnoDB
     Support: YES
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
  Savepoints: YES
*************************** 4. row ***************************
      Engine: BerkeleyDB
     Support: YES
     Comment: Supports transactions and page-level locking
Transactions: YES
```

```
          XA: NO
  Savepoints: NO
*************************** 5. row ***************************
      Engine: EXAMPLE
     Support: YES
     Comment: Example storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 6. row ***************************
      Engine: ARCHIVE
     Support: YES
     Comment: Archive storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 7. row ***************************
      Engine: CSV
     Support: YES
     Comment: CSV storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 8. row ***************************
      Engine: BLACKHOLE
     Support: YES
     Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 9. row ***************************
      Engine: FEDERATED
     Support: YES
     Comment: Federated MySQL storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 10. row ***************************
      Engine: MRG_MYISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO
```

A `Support` value indicates whether the particular storage engine is supported, and which is the default engine. For example, if the server is started with the `--default-table-type=InnoDB` option, then the `Support` value for the `InnoDB` row has the value `DEFAULT`. See Chapter 15, *Storage Engines and Table Types*.

The `Transactions`, `XA`, and `Savepoints` columns were added in MySQL 5.1.2.

13.5.4.9. `SHOW ERRORS` Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

This statement is similar to `SHOW WARNINGS`, except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.7, "`SELECT` Syntax".

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

For more information, see Section 13.5.4.22, "`SHOW WARNINGS` Syntax".

13.5.4.10. `SHOW GRANTS` Syntax

```
SHOW GRANTS FOR user
```

This statement lists the `GRANT` statements that must be issued to duplicate the privileges that are granted to a MySQL user account.

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                           |
+---------------------------------------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+---------------------------------------------------------------------+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

13.5.4.11. `SHOW INDEX` Syntax

```
SHOW INDEX FROM tbl_name [FROM db_name]
```

`SHOW INDEX` returns table index information in a format that resembles the `SQLStatistics` call in ODBC.

`SHOW INDEX` returns the following fields:

- `Table`

  The name of the table.

- `Non_unique`

  0 if the index cannot contain duplicates, 1 if it can.

- `Key_name`

  The name of the index.

- `Seq_in_index`

  The column sequence number in the index, starting with 1.

- `Column_name`

  The column name.

- `Collation`

  How the column is sorted in the index. In MySQL, this can have values 'A' (Ascending) or `NULL` (Not sorted).

- `Cardinality`

  An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `Sub_part`

  The number of indexed characters if the column is only partly indexed. `NULL` if the entire column is indexed.

- `Packed`

  Indicates how the key is packed. `NULL` if it is not.

- `Null`

  Contains `YES` if the column may contain `NULL`. If not, the column contains `NO`.

- `Index_type`

  The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- `Comment`

  Various remarks.

You can use *`db_name.tbl_name`* as an alternative to the *`tbl_name`* `FROM` *`db_name`* syntax. These two statements are equivalent:

```
mysql> SHOW INDEX FROM mytable FROM mydb;
mysql> SHOW INDEX FROM mydb.mytable;
```

`SHOW KEYS` is a synonym for `SHOW INDEX`. You can also list a table's indexes with the `mysqlshow -k` *`db_name tbl_name`* command.

13.5.4.12. SHOW INNODB STATUS Syntax

```
SHOW INNODB STATUS
```

In MySQL 5.1, this is a deprecated synonym for `SHOW ENGINE INNODB STATUS`. See Section 13.5.4.7, "`SHOW ENGINE` Syntax".

13.5.4.13. SHOW LOGS Syntax

```
SHOW [BDB] LOGS
```

In MySQL 5.1, this is a deprecated synonym for `SHOW ENGINE BDB LOGS`. See Section 13.5.4.7, "`SHOW ENGINE` Syntax".

13.5.4.14. SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See Section 7.4.9, “How MySQL Opens and Closes Tables”.

`SHOW OPEN TABLES` returns the following fields:

- `Database`

  The database containing the table.

- `Table`

  The table name.

- `In_use`

  The number of times the table currently is in use by queries. If the count is zero, the table is open, but not currently being used.

- `Name_locked`

  Whether table name is locked. Name-locking is used for operations such as dropping or renaming tables.

13.5.4.15. `SHOW PRIVILEGES` Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact output depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
*************************** 1. row ***************************
Privilege: Alter
Context: Tables
Comment: To alter the table
*************************** 2. row ***************************
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
*************************** 3. row ***************************
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
*************************** 4. row ***************************
Privilege: Create routine
Context: Functions,Procedures
Comment: To use CREATE FUNCTION/PROCEDURE
*************************** 5. row ***************************
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
*************************** 6. row ***************************
Privilege: Create view
Context: Tables
Comment: To create new views
*************************** 7. row ***************************
Privilege: Create user
Context: Server Admin
Comment: To create new users
*************************** 8. row ***************************
Privilege: Delete
Context: Tables
Comment: To delete existing rows
```

```
*************************** 9. row ***************************
Privilege: Drop
Context: Databases,Tables
Comment: To drop databases, tables, and views
*************************** 10. row ***************************
Privilege: Execute
Context: Functions,Procedures
Comment: To execute stored routines
*************************** 11. row ***************************
Privilege: File
Context: File access on server
Comment: To read and write files on the server
*************************** 12. row ***************************
Privilege: Grant option
Context: Databases,Tables,Functions,Procedures
Comment: To give to other users those privileges you possess
*************************** 13. row ***************************
Privilege: Index
Context: Tables
Comment: To create or drop indexes
*************************** 14. row ***************************
Privilege: Insert

Privilege: Update
```

```
Context: Tables
Comment: To update existing rows
*************************** 27. row ***************************
Privilege: Usage
Context: Server Admin
Comment: No privileges - allow connect only
```

13.5.4.16. SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

SHOW PROCESSLIST shows you which threads are running. You can also get this information using the mysqladmin processlist statement. If you have the SUPER privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). See Section 13.5.5.3, "KILL Syntax". If you do not use the FULL keyword, only the first 100 characters of each query are shown.

This statement is very useful if you get the "too many connections" error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the SUPER privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

The output of SHOW PROCESSLIST may look like this:

```
mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
*************************** 2. row ***************************
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave I/O thread to update it
Info: NULL
*************************** 3. row ***************************
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
*************************** 4. row ***************************
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
*************************** 5. row ***************************
Id: 3123
User: stefan
Host: localhost
db: apollon
```

```
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)
```

The columns have the following meaning:

- `Id`: The connection identifier
- `User`: The MySQL user who is issuing the statement

  If the user is `system user`, it can be either of these:

  - `SYSTEM_THREAD_DELAYED_INSERT`
  - `SYSTEM_THREAD_SLAVE_IO`
  - `SYSTEM_THREAD_SLAVE_SQL`

  For the `system user`, there's no host specified in the `Host` column.
- `Host`: The host of the client issuing the statement (except for `system user` where there is no host)

  `SHOW PROCESSLIST` reports the hostname for TCP/IP connections in *`host_name`*`:`*`client_port`* format to make it easier to determine which client is doing what.
- `db`: The default database, if selected, otherwise `NULL`
- `Command`: The value of that column corresponds to the `COM_`*`xxx`* commands of the client/server protocol; see Section 5.3.4, “Server Status Variables”

  The `Command` value may be one of the following: `Binlog Dump`, `Change user`, `Close stmt`, `Connect`, `Connect Out`, `Create DB`, `Debug`, `Delayed insert`, `Drop DB`, `Error`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`
- `Time`: The time in seconds between the start of the statement or command and now
- `State`: An action, event, or state which can be one of the following: `After create`, `Analyzing`, `Changing master`, `Checking master version`, `Checking table`, `Connecting to master`, `Copying to group table`, `Copying to tmp table`, `Creating delayed handler`, `Creating index`, `Creating sort index`, `Creating table from master dump`, `Creating tmp table`, `Execution of init_command`, `FULLTEXT initialization`, `Finished reading one binlog; switching to next binlog`, `Flushing tables`, `Killed`, `Killing slave`, `Locked`, `Making temp file `, `Opening master dump table`, `Opening table`, `Opening tables`, `Processing request`, `Purging old relay logs`, `Queueing master event to the relay log`, `Reading event from the relay log`, `Reading from net`, `Reading master dump table data`, `Rebuilding the index on master dump table`, `Reconnecting after a failed binlog dump request`, `Reconnecting after a failed master event read`, `Registering slave on master`, `Removing duplicates`, `Reopen tables`, `Repair by sorting`, `Repair done`, `Repair with keycache`, `Requesting binlog dump`, `Rolling back`, `Saving state`, `Searching rows for update`, `Sending binlog event to slave`, `Sending data`, `Sorting for group`, `Sorting for order`, `Sorting index`, `Sorting result`, `System lock`, `Table lock`, `Thread initialized`, `Updating`, `User lock`, `Waiting for INSERT`, `Waiting for master to send event`, `Waiting for master update`, `Waiting for slave mutex on exit`, `Waiting for table`, `Waiting for tables`, `Waiting for the next event in relay log`, `Waiting on cond`, `Waiting to finalize`

termination, Waiting to reconnect after a failed binlog dump request, Waiting to reconnect after a failed master event read, Writing to net, allocating local table, cleaning up, closing tables, converting HEAP to MyISAM, copy to tmp table, creating table, deleting from main table, deleting from reference tables, discard_or_import_tablespace, end, freeing items, got handler lock, got old table, info, init, insert, logging slow query, login, preparing, purging old relay logs, query end, removing tmp table, rename, rename result table, reschedule, setup, starting slave, statistics, storing row into queue, update, updating, updating main table, updating reference tables, upgrading lock, waiting for delay_list, waiting for handler insert, waiting for handler lock, waiting for handler open

The most common State values are described in the rest of this section. Most of the other State values are useful only for finding bugs in the server.

For the SHOW PROCESSLIST statement, the value of State is NULL.

- Info: The query that the thread was issuing, but only if that query was still running by the time SHOW PROCESSLIST was issued (this is always the case for the SHOW PROCESSLIST statement itself, and for long-running queries)

Some states commonly seen in the output from SHOW PROCESSLIST:

- Checking table

  The thread is performing (automatic) checking of the table.

- Closing tables

  Means that the thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, then you should verify that you do not have a full disk and that the disk is not in very heavy use.

- Connect Out

  Slave connecting to master.

- Copying to tmp table

  The server is copying to a temporary table in memory.

- Copying to tmp table on disk

  The server is copying to a temporary table on disk. The temporary result set was larger than tmp_table_size and the thread is changing the temporary table from in-memory to disk-based format to save memory.

- Creating tmp table

  The thread is creating a temporary table to hold a part of the result for the query.

- deleting from main table

  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving fields and offsets to be used for deleting from the other (reference) tables.

- deleting from reference tables

  The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `Flushing tables`

  The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.

- `FULLTEXT initialization`

  The server is preparing to perform a natural-language full-text search.

- `Killed`

  Someone has sent a `KILL` command to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `Locked`

  The query is locked by another query.

- `Sending data`

  The thread is processing rows for a `SELECT` statement and also is sending data to the client.

- `Sorting for group`

  The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

  The thread is doing a sort to satisfy a `ORDER BY`.

- `Opening tables`

  The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished.

- `Reading from net`

  The server is reading a packet from the network.

- `Removing duplicates`

  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `Reopen table`

  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

  The repair code is using a sort to create indexes.

- `Repair with keycache`

  The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Searching rows for update`

  The thread is doing a first phase to find all matching rows before updating them. This has to be

done if the UPDATE is changing the index that is used to find the involved rows.

- Sleeping

  The thread is waiting for the client to send a new statement to it.

- statistics

  The server is calculating statistics to develop a query execution plan.

- System lock

  The thread is waiting to get an external system lock for the table. If you are not using multiple mysqld servers that are accessing the same tables, you can disable system locks with the --skip-external-locking option.

- Upgrading lock

  The INSERT DELAYED handler is trying to get a lock for the table to insert rows.

- Updating

  The thread is searching for rows to update and updating them.

- updating main table

  The server is executing the first part of a multiple-table update. It is updating only the first table, and saving fields and offsets to be used for updating the other (reference) tables.

- updating reference tables

  The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- User Lock

  The thread is waiting on a GET_LOCK().

- Waiting for tables

  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to be able to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used FLUSH TABLES or one of the following statements on the table in question: FLUSH TABLES *tbl_name*, ALTER TABLE, RENAME TABLE, REPAIR TABLE, ANALYZE TABLE, or OPTIMIZE TABLE.

- waiting for handler insert

  The INSERT DELAYED handler has processed all pending inserts and is waiting for new ones.

- Writing to net

  The server is writing a packet to the network.

Most states correspond to very quick operations. If a thread stays in any of these states for many seconds, there might be a problem that needs to be investigated.

13.5.4.17. SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
```

`SHOW STATUS` provides server status information. This information also can be obtained using the `mysqladmin extended-status` command.

Partial output is shown here. The list of variables and their values may be different for your server. The meaning of each variable is given in Section 5.3.4, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
...                       ...          ...
| Open_tables              | 1          |
| Open_files               | 2          |
| Open_streams             | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
...                       ...          ...
| Table_locks_immediate    | 1920382    |
| Table_locks_waited       | 0          |
| Threads_cached           | 0          |
| Threads_created          | 30022      |
| Threads_connected        | 1          |
| Threads_running          | 1          |
| Uptime                   | 80380      |
+--------------------------+------------+
```

With a `LIKE` clause, the statement displays only those variables that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------+----------+
| Variable_name      | Value    |
+--------------------+----------+
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |
+--------------------+----------+
```

With the `GLOBAL` option, you get the status values for all connections to MySQL. With `SESSION`, you get the status values for the current connection. If you use neither option, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

Note that some status variables have only a global value. For these you get the same value for both `GLOBAL` and `SESSION`.

13.5.4.18. SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLE STATUS` works likes `SHOW TABLE`, but provides a lot of information about each table. You can also get this list using the `mysqlshow --status db_name` command.

This statement also displays information about views.

For NDB Cluster tables, the output of this statement shows appropriate values for the Avg_row_length and Data_length columns, with the exception that BLOB columns are not taken into account. In addition, the number of replicas is shown in the Comment column (as number_of_replicas).

SHOW TABLE STATUS returns the following fields:

- Name

  The name of the table.

- Engine

  The storage engine for the table. Before MySQL 4.1.2, this value is labeled as Type. See Chapter 15, *Storage Engines and Table Types*.

- Version

  The version number of the table's .frm file.

- Row_format

  The row storage format (Fixed, Dynamic, Compressed, Redundant, Compact). The format of InnoDB tables is reported as Redundant or Compact.

- Rows

  The number of rows. Some storage engines, such as MyISAM, store the exact count.

  For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use SELECT COUNT(*) to obtain an accurate count.

  The Rows value is NULL for tables in the INFORMATION_SCHEMA database.

- Avg_row_length

  The average row length.

- Data_length

  The length of the data file.

- Max_data_length

  The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

- Index_length

  The length of the index file.

- Data_free

  The number of allocated but unused bytes.

- Auto_increment

  The next AUTO_INCREMENT value.

- Create_time

  When the table was created.

- `Update_time`

  When the data file was last updated.

- `Check_time`

  When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- `Collation`

  The table's character set and collation.

- `Checksum`

  The live checksum value (if any).

- `Create_options`

  Extra options used with `CREATE TABLE`.

- `Comment`

  The comment used when creating the table (or information as to why MySQL could not access the table information).

In the table comment, `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table.

For `MEMORY` (`HEAP`) tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `view`.

13.5.4.19. `SHOW TABLES` Syntax

```
SHOW [FULL] TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLES` lists the non-`TEMPORARY` tables in a given database. You can also get this list using the `mysqlshow db_name` command.

This command also lists any views in the database. The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

Note: If you have no privileges for a table, the table does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

13.5.4.20. `SHOW TRIGGERS` Syntax

```
SHOW TRIGGERS [FROM db_name] [LIKE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined on the MySQL server.

For the trigger `ins_sum` as defined in Section 21.3, “Using Triggers”, the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
*************************** 1. row ***************************
  Trigger: ins_sum
    Event: INSERT
    Table: account
Statement: SET @sum = @sum + NEW.amount
   Timing: BEFORE
  Created: NULL
 sql_mode:
  Definer: myname@localhost
```

Note: When using a `LIKE` clause with `SHOW TRIGGERS`, the expression to be matched (*`expr`*) is compared with the name of the table on which the trigger is declared, and not with the name of the trigger:

```
mysql> SHOW TRIGGERS LIKE 'ins%';
Empty set (0.01 sec)
```

A brief explanation of the columns in the output of this statement is shown here:

- `Trigger`: The name of the trigger.
- `Event`: The event invoking the trigger. Must be one of `'INSERT'`, `'UPDATE'`, or `'DELETE'`.
- `Table`: The table for which the trigger is defined.
- `Statement`: The statement to be executed when the trigger is invoked. This is the same as the text shown in the `ACTION_STATEMENT` column of `INFORMATION_SCHEMA.TRIGGERS`.
- `Timing`: One of the two values `'BEFORE'` or `'AFTER'`.
- `Created`: Currently the value of this column is always `NULL`.
- `sql_mode`: The SQL mode in effect when the trigger executes.
- `Definer`: The account that created the trigger.

You must have the `SUPER` privilege in order to execute `SHOW TRIGGERS`.

See also Section 23.1.16, “The `INFORMATION_SCHEMA TRIGGERS` Table”.

13.5.4.21. `SHOW VARIABLES` Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
```

`SHOW VARIABLES` shows the values of some MySQL system variables. This information also can be obtained using the `mysqladmin variables` command.

With the `GLOBAL` option, you obtain the values that are used for new connections to MySQL. With `SESSION`, you get the values that are in effect for the current connection. If you use neither option, the default is `SESSION`.

`LOCAL` is a synonym for `SESSION`.

If the default values are unsuitable, you can set most of these variables using command-line options when `mysqld` starts or at runtime with the `SET` statement. See Section 5.3.1, “`mysqld` Command-Line Options”, and Section 13.5.3, “`SET` Syntax”.

Partial output is shown here. The list of variables and their values may be different for your server.

The meaning of each variable is given in Section 5.3.3, “Server System Variables”. Information about tuning them is provided in Section 7.5.2, “Tuning Server Parameters”.

```
mysql> SHOW VARIABLES;
+---------------------------------+-----------------------------------------
| Variable_name                   | Value
+---------------------------------+-----------------------------------------
| auto_increment_increment        | 1
| auto_increment_offset           | 1
| automatic_sp_privileges         | ON
| back_log                        | 50
| basedir                         | /home/jon/bin/mysql-5.1/
| binlog_cache_size               | 32768
| bulk_insert_buffer_size         | 8388608
| character_set_client            | latin1
| character_set_connection        | latin1
...                               ...
| max_user_connections            | 0
| max_write_lock_count            | 4294967295
| multi_range_count               | 256
| myisam_data_pointer_size        | 6
| myisam_max_sort_file_size       | 2147483647
| myisam_recover_options          | OFF
| myisam_repair_threads           | 1
| myisam_sort_buffer_size         | 8388608
| ndb_autoincrement_prefetch_sz   | 32
| ndb_cache_check_time            | 0
| ndb_force_send                  | ON
...                               ...
| time_zone                       | SYSTEM
| timed_mutexes                   | OFF
| tmp_table_size                  | 33554432
| tmpdir                          |
| transaction_alloc_block_size    | 8192
| transaction_prealloc_size       | 4096
| tx_isolation                    | REPEATABLE-READ
| updatable_views_with_limit      | YES
| version                         | 5.1.2-alpha-log
| version_comment                 | Source distribution
| version_compile_machine         | i686
| version_compile_os              | suse-linux
| wait_timeout                    | 28800
+---------------------------------+-----------------------------------------
```

With a `LIKE` clause, the statement displays only those variables that match the pattern:

```
mysql> SHOW VARIABLES LIKE 'have%';
+----------------------+----------+
| Variable_name        | Value    |
+----------------------+----------+
| have_archive         | YES      |
| have_bdb             | NO       |
| have_blackhole_engine | YES      |
| have_compress        | YES      |
| have_crypt           | YES      |
| have_csv             | YES      |
| have_example_engine  | NO       |
| have_federated_engine | NO       |
| have_geometry        | YES      |
| have_innodb          | YES      |
| have_isam            | NO       |
| have_ndbcluster      | DISABLED |
| have_openssl         | NO       |
| have_partition_engine | YES      |
| have_query_cache     | YES      |
| have_raid            | NO       |
| have_rtree_keys      | YES      |
| have_symlink         | YES      |
```

```
+----------------------+----------+
```

13.5.4.22. SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` shows the error, warning, and note messages that resulted from the last statement that generated messages, or nothing if the last statement that used a table generated no messages. A related statement, `SHOW ERRORS`, shows only the errors. See Section 13.5.4.9, "`SHOW ERRORS` Syntax".

The list of messages is reset for each new statement that uses a table.

The `SHOW COUNT(*) WARNINGS` statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of `warning_count` might be greater than the number of messages displayed by `SHOW WARNINGS` if the `max_error_count` system variable is set so low that not all messages are stored. An example shown later in this section demonstrates how this can happen.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.7, "`SELECT` Syntax".

The MySQL server sends back the total number of errors, warnings, and notes resulting from the last statement. If you are using the C API, this value can be obtained by calling `mysql_warning_count()`. See Section 25.2.3.69, "`mysql_warning_count()`".

Warnings are generated for statements such as `LOAD DATA INFILE` and DML statements such as `INSERT`, `UPDATE`, `CREATE TABLE`, and `ALTER TABLE`.

The following `DROP TABLE` statement results in a note:

```
mysql> DROP TABLE IF EXISTS no_such_table;
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Note  | 1051 | Unknown table 'no_such_table' |
+-------+------+-----------------------------+
```

Here is a simple example that shows a syntax warning for `CREATE TABLE` and conversion warnings for `INSERT`:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4)) TYPE=MyISAM;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1287
Message: 'TYPE=storage_engine' is deprecated, use
         'ENGINE=storage_engine' instead
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'),(NULL,'test'),
    -> (300,'Open Source');
Query OK, 3 rows affected, 4 warnings (0.01 sec)
Records: 3  Duplicates: 0  Warnings: 4

mysql> SHOW WARNINGS\G
```

```
*************************** 1. row ***************************
  Level: Warning
   Code: 1265
Message: Data truncated for column 'b' at row 1
*************************** 2. row ***************************
  Level: Warning
   Code: 1263
Message: Data truncated, NULL supplied to NOT NULL column 'a' at row 2
*************************** 3. row ***************************
  Level: Warning
   Code: 1264
Message: Data truncated, out of range for column 'a' at row 3
*************************** 4. row ***************************
  Level: Warning
   Code: 1265
Message: Data truncated for column 'b' at row 3
4 rows in set (0.00 sec)
```

The maximum number of error, warning, and note messages to store is controlled by the `max_error_count` system variable. By default, its value is 64. To change the number of messages you want stored, change the value of `max_error_count`. In the following example, the `ALTER TABLE` statement produces three warning messages, but only one is stored because `max_error_count` has been set to `1`:

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+
1 row in set (0.00 sec)

mysql> SET max_error_count=1;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
|               3 |
+-----------------+
1 row in set (0.01 sec)

mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)
```

To disable warnings, set `max_error_count` to `0`. In this case, `warning_count` still indicates how many warnings have occurred, but none of the messages are stored.

You can set the `SQL_NOTES` session variable to `0` to cause `Note`-level warnings not to be recorded.

13.5.5. Other Administrative Statements

13.5.5.1. `CACHE INDEX` Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

The CACHE INDEX statement assigns table indexes to a specific key cache. It is used only for MyISAM tables.

The following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

The syntax of CACHE INDEX allows you to specify that only particular indexes from a table should be assigned to the cache. However, the current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a CACHE INDEX statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See Section 9.4.1, “Structured System Variables”.

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter what client issues the queries.

13.5.5.2. FLUSH Syntax

```
FLUSH [LOCAL | NO_WRITE_TO_BINLOG] flush_option [, flush_option] ...
```

You should use the FLUSH statement if you want to clear some of the internal caches MySQL uses. To execute FLUSH, you must have the RELOAD privilege.

flush_option can be any of the following:

- HOSTS

  Empties the host cache tables. You should flush the host tables if some of your hosts change IP number or if you get the error message Host *host_name* is blocked. When more than

`max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host tables allows the host to attempt to connect again. See Section A.2.5, "`Host 'host_name' is blocked`". You can start `mysqld` with `--max_connect_errors=999999999` to avoid this error message.

- `DES_KEY_FILE`

  Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `LOGS`

  Closes and reopens all log files. If you have specified an update log file or a binary log file without an extension, the extension number of the log file is incremented by one relative to the previous file. If you have used an extension in the file name, MySQL closes and reopens the log file. On Unix, this is the same thing as sending a `SIGHUP` signal to the `mysqld` server (except on some Mac OS X 10.3 versions where `mysqld` ignores `SIGHUP` and `SIGQUIT`).

  If the server was started with the `--log-error` option, `FLUSH LOGS` causes the error log is renamed with a suffix of `-old` and `mysqld` creates a new empty log file. No renaming occurs if the `--log-error` option was not given.

- `PRIVILEGES`

  Reloads the privileges from the grant tables in the `mysql` database.

- `QUERY CACHE`

  Defragment the query cache to better utilize its memory. This statement does not remove any queries from the cache, unlike `RESET QUERY CACHE`.

- `STATUS`

  Resets most status variables to zero. This is something you should use only when debugging a query. See Section 1.8, "How to Report Bugs or Problems".

- `{TABLE | TABLES} [`*`tbl_name`*` [, `*`tbl_name`*`] ...]`

  When no tables are named, closes all open tables and forces all tables in use to be closed. This also flushes the query cache. With one or more table names, flushes only the given tables. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

- `TABLES WITH READ LOCK`

  Closes all open tables and locks all tables for all databases with a read lock until you execute `UNLOCK TABLES`. This is very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

- `USER_RESOURCES`

  Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See Section 13.5.1.3, "`GRANT` and `REVOKE` Syntax".

`FLUSH` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. **Note**: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any case because they would cause problems if replicated to a slave.

You can also access some of these statements with the `mysqladmin` utility, using the `flush-`

`hosts`, `flush-logs`, `flush-privileges`, `flush-status`, or `flush-tables` commands.

Note: It is not possible in MySQL 5.1.5-alpha to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section I.1, “Restrictions on Stored Routines and Triggers”.

See also Section 13.5.5.5, “`RESET` Syntax”, for information about how the `RESET` statement is used with replication.

13.5.5.3. `KILL` Syntax

```
KILL [CONNECTION | QUERY] thread_id
```

Each connection to `mysqld` runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL` *`thread_id`* statement.

`KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *`thread_id`*.
- `KILL QUERY` terminates the statement that the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

Note: You cannot use `KILL` with the Embedded MySQL Server library, because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you do a `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die, because the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a "disk full" error message.
- **Warning**: Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you

optimize or repair it again (without interruption).

13.5.5.4. LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
    [[INDEX|KEY] (index_name[, index_name] ...)]
    [IGNORE LEAVES]
```

The LOAD INDEX INTO CACHE statement preloads a table index into the key cache to which it has been assigned by an explicit CACHE INDEX statement, or into the default key cache otherwise. LOAD INDEX INTO CACHE is used only for MyISAM tables.

The IGNORE LEAVES modifier causes only blocks for the non-leaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes for the tables t1 and t2:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

This statement preloads all index blocks from t1. It preloads only blocks for the non-leaf nodes from t2.

The syntax of LOAD INDEX INTO CACHE allows you to specify that only particular indexes from a table should be preloaded. However, the current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

13.5.5.5. RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The RESET statement is used to clear the state of various server operations. It also acts as a stronger version of the FLUSH statement. See Section 13.5.5.2, “FLUSH Syntax”.

You must have the RELOAD privilege in order to execute RESET.

reset_option can be any of the following:

- MASTER

  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. (Known as FLUSH MASTER in previous versions of MySQL.) See Section 13.6.1, “SQL Statements for Controlling Master Servers”.

- QUERY CACHE

  Removes all query results from the query cache.

- SLAVE

  Makes the slave forget its replication position in the master binary logs. Also resets the relay log

by deleting any existing relay log files and beginning a new one. (Known as FLUSH SLAVE in previous versions of MySQL.) See Section 13.6.2, “SQL Statements for Controlling Slave Servers”.

13.6. Replication Statements

This section describes SQL statements related to replication. One group of statements is used for controlling master servers. The other is used for controlling slave servers.

13.6.1. SQL Statements for Controlling Master Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing master replication servers. Section 13.6.2, “SQL Statements for Controlling Slave Servers”, discusses statements for managing slave servers.

13.6.1.1. PURGE MASTER LOGS Syntax

```
PURGE {MASTER | BINARY} LOGS TO 'log_name'
PURGE {MASTER | BINARY} LOGS BEFORE 'date'
```

Deletes all the binary logs listed in the log index prior to the specified log or date. The logs also are removed from the list recorded in the log index file, so that the given log becomes the first.

Example:

```
PURGE MASTER LOGS TO 'mysql-bin.010';
PURGE MASTER LOGS BEFORE '2003-04-02 22:46:26';
```

The BEFORE variant's *date* argument can be in 'YYYY-MM-DD hh:mm:ss' format. MASTER and BINARY are synonyms.

If you have an active slave that currently is reading one of the logs you are trying to delete, this statement does nothing and fails with an error. However, if a slave is dormant and you happen to purge one of the logs it wants to read, the slave is unable to replicate once it comes up. The statement is safe to run while slaves are replicating. You do not need to stop them.

To purge logs, follow this procedure:

1. On each slave server, use SHOW SLAVE STATUS to check which log it is reading.
2. Obtain a listing of the logs on the master server with SHOW MASTER LOGS.
3. Determine the earliest log among all the slaves. This is the target log. If all the slaves are up to date, this is the last log on the list.
4. Make a backup of all the logs you are about to delete. (This step is optional, but always advisable.)
5. Purge all logs up to but not including the target log.

13.6.1.2. RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and cre-

ates a new binary log file.

13.6.1.3. SET SQL_LOG_BIN Syntax

```
SET SQL_LOG_BIN = {0|1}
```

Disables or enables binary logging for the current connection (SQL_LOG_BIN is a session variable) if the client connects using an account that has the SUPER privilege. A statement is refused with an error if the client does not have that privilege.

13.6.1.4. SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
   [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.7, "SELECT Syntax".

Note: Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process as the server dumps the complete contents of the binary log (which includes most of the queries executed by MySQL) to stdout. To save the binary log to a text file for later examination and analysis, use the mysqlbinlog utility. See Section 8.6, "mysqlbinlog — Utility for Processing Binary Log Files".

13.6.1.5. SHOW MASTER LOGS Syntax

```
SHOW MASTER LOGS
SHOW BINARY LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.6.1.1, "PURGE MASTER LOGS Syntax", for determining which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 |    724935 |
| binlog.000016 |    733481 |
+---------------+-----------+
```

SHOW BINARY LOGS is equivalent to SHOW MASTER LOGS.

13.6.1.6. SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

Provides status information on the binary log files of the master. Example:

```
mysql > SHOW MASTER STATUS;
+---------------+----------+--------------+------------------+
| File          | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+---------------+----------+--------------+------------------+
| mysql-bin.003 | 73       | test         | manual,mysql     |
+---------------+----------+--------------+------------------+
```

13.6.1.7. SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master. Any slave not started with the `--report-host=slave_name` option is not visible in this list.

13.6.2. SQL Statements for Controlling Slave Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing slave replication servers. Section 13.6.1, “SQL Statements for Controlling Master Servers”, discusses statements for managing master servers.

13.6.2.1. CHANGE MASTER TO Syntax

```
  CHANGE MASTER TO master_def [, master_def] ...

master_def:
      MASTER_HOST = 'host_name'
    | MASTER_USER = 'user_name'
    | MASTER_PASSWORD = 'password'
    | MASTER_PORT = port_num
    | MASTER_CONNECT_RETRY = count
    | MASTER_LOG_FILE = 'master_log_name'
    | MASTER_LOG_POS = master_log_pos
    | RELAY_LOG_FILE = 'relay_log_name'
    | RELAY_LOG_POS = relay_log_pos
    | MASTER_SSL = {0|1}
    | MASTER_SSL_CA = 'ca_file_name'
    | MASTER_SSL_CAPATH = 'ca_directory_name'
    | MASTER_SSL_CERT = 'cert_file_name'
    | MASTER_SSL_KEY = 'key_file_name'
    | MASTER_SSL_CIPHER = 'cipher_list'
```

Changes the parameters that the slave server uses for connecting to and communicating with the master server.

`MASTER_USER`, `MASTER_PASSWORD`, `MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, and `MASTER_SSL_CIPHER` provide information to the slave about how to connect to its master.

The SSL options (`MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, and `MASTER_SSL_CIPHER`) can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored until you use a server that has SSL support enabled.

If you don't specify a given parameter, it keeps its old value, except as indicated in the following discussion. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
mysql> STOP SLAVE; -- if replication was running
mysql> CHANGE MASTER TO MASTER_PASSWORD='new3cret';
mysql> START SLAVE; -- if you want to restart replication
```

There is no need to specify the parameters that do not change (host, port, user, and so forth).

`MASTER_HOST` and `MASTER_PORT` are the hostname (or IP address) of the master host and its TCP/IP port. Note that if `MASTER_HOST` is equal to `localhost`, then, like in other parts of MySQL, the port may be ignored (if Unix socket files can be used, for example).

If you specify `MASTER_HOST` or `MASTER_PORT`, the slave assumes that the master server is dif-

ferent than before (even if you specify a host or port value that is the same as the current value.) In this case, the old values for the master binary log name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. If you specify either of them, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` are specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

`CHANGE MASTER` *deletes all relay log files* and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay logs are kept; the `relay_log_purge` global variable is set silently to `0`.

`CHANGE MASTER TO` updates the contents of the `master.info` and `relay-log.info` files.

`CHANGE MASTER` is useful for setting up a slave when you have the snapshot of the master and have recorded the log and the offset corresponding to it. After loading the snapshot into the slave, you can run `CHANGE MASTER TO MASTER_LOG_FILE='`*`log_name_on_master`*`', MASTER_LOG_POS=`*`log_offset_on_master`* on the slave.

Examples:

```
mysql> CHANGE MASTER TO
    ->     MASTER_HOST='master2.mycompany.com',
    ->     MASTER_USER='replication',
    ->     MASTER_PASSWORD='bigs3cret',
    ->     MASTER_PORT=3306,
    ->     MASTER_LOG_FILE='master2-bin.001',
    ->     MASTER_LOG_POS=4,
    ->     MASTER_CONNECT_RETRY=10;

mysql> CHANGE MASTER TO
    ->     RELAY_LOG_FILE='slave-relay-bin.006',
    ->     RELAY_LOG_POS=4025;
```

The first example changes the master and master's binary log coordinates. This is used when you want to set up the slave to replicate the master.

The second example shows an operation that is less frequently employed. It is used when the slave has relay logs that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`).

You can even use the second operation in a non-replication setup with a standalone, non-slave server for recovery following a crash. Suppose that your server has crashed and you have restored a backup. You want to replay the server's own binary logs (not relay logs, but regular binary logs), named (for example) `myhost-bin.*`. First, make a backup copy of these binary logs in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary logs. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option, Instead, use the `--replicate-same-server-id`, `--relay-log=myhost-bin` (to make the server believe that these regular binary logs are relay logs) and `--skip-slave-start` options. Once the server starts, issue these statements:

```
mysql> CHANGE MASTER TO
    ->     RELAY_LOG_FILE='myhost-bin.153',
    ->     RELAY_LOG_POS=410,
    ->     MASTER_HOST='some_dummy_string';
mysql> START SLAVE SQL_THREAD;
```

The server reads and executes its own binary logs, thus achieving crash recovery. Once the recovery

is finished, run STOP SLAVE, shut down the server, delete master.info and relay-log.info, and restart the server with its original options.

Specifying MASTER_HOST (even with a dummy value) is required to make the server think it is a slave.

13.6.2.2. LOAD DATA FROM MASTER Syntax

```
LOAD DATA FROM MASTER
```

This command takes a snapshot of the master and copies it to the slave. It updates the values of MASTER_LOG_FILE and MASTER_LOG_POS so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the --replicate-*-do-* and --replicate-*-ignore-* options are honored. --replicate-rewrite-db is *not* taken into account because a user could use this option to set up a non-unique mapping such as --replicate-rewrite-db=db1->db3 and --replicate-rewrite-db=db2->db3, which would confuse the slave when loading tables from the master.

Use of this statement is subject to the following conditions:

- It works only with MyISAM tables. Attempting to load a non-MyISAM table results in the following error:

  ```
  ERROR 1189 (08S01): Net error reading from master
  ```

- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

If you are loading large tables, you might have to increase the values of net_read_timeout and net_write_timeout on both the master and slave servers. See Section 5.3.3, “Server System Variables”.

Note that LOAD DATA FROM MASTER does *not* copy any tables from the mysql database. This makes it easy to have different users and privileges on the master and the slave.

The LOAD DATA FROM MASTER statement requires the replication account that is used to connect to the master to have the RELOAD and SUPER privileges on the master and the SELECT privilege for all master tables you want to load. All master tables for which the user does not have the SELECT privilege are ignored by LOAD DATA FROM MASTER. This is because the master hides them from the user: LOAD DATA FROM MASTER calls SHOW DATABASES to know the master databases to load, but SHOW DATABASES returns only databases for which the user has some privilege. See Section 13.5.4.6, “SHOW DATABASES Syntax”. On the slave side, the user that issues LOAD DATA FROM MASTER should have grants to drop and create the databases and tables that are copied.

13.6.2.3. LOAD TABLE *tbl_name* FROM MASTER Syntax

```
LOAD TABLE tbl_name FROM MASTER
```

Transfers a copy of the table from the master to the slave. This statement is implemented mainly for debugging of LOAD DATA FROM MASTER. It requires that the account used for connecting to the master server has the RELOAD and SUPER privileges on the master and the SELECT privilege on the master table to load. On the slave side, the user that issues LOAD TABLE FROM MASTER should have privileges to drop and create the table.

The conditions for LOAD DATA FROM MASTER apply here as well. For example, LOAD TABLE FROM MASTER works only for MyISAM tables. The timeout notes for LOAD DATA FROM MASTER apply as well.

13.6.2.4. MASTER_POS_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos)
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See Section 12.9.4, “Miscellaneous Functions”, for a full description.

13.6.2.5. RESET SLAVE Syntax

```
RESET SLAVE
```

Makes the slave forget its replication position in the master's binary logs. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay logs, and starts a new relay log.

Note: All relay logs are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

Connection information stored in the `master.info` file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

13.6.2.6. SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = n
```

Skip the next *n* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave thread is not running. Otherwise, it produces an error.

13.6.2.7. SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS
```

Provides status information on essential parameters of the slave threads. If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
       Slave_IO_State: Waiting for master to send event
          Master_Host: localhost
          Master_User: root
          Master_Port: 3306
        Connect_Retry: 3
      Master_Log_File: gbichot-bin.005
  Read_Master_Log_Pos: 79
       Relay_Log_File: gbichot-relay-bin.005
        Relay_Log_Pos: 548
Relay_Master_Log_File: gbichot-bin.005
     Slave_IO_Running: Yes
    Slave_SQL_Running: Yes
      Replicate_Do_DB:
  Replicate_Ignore_DB:
           Last_Errno: 0
```

```
           Last_Error:
         Skip_Counter: 0
  Exec_Master_Log_Pos: 79
      Relay_Log_Space: 552
      Until_Condition: None
       Until_Log_File:
        Until_Log_Pos: 0
   Master_SSL_Allowed: No
   Master_SSL_CA_File:
   Master_SSL_CA_Path:
      Master_SSL_Cert:
    Master_SSL_Cipher:
       Master_SSL_Key:
Seconds_Behind_Master: 8
```

`SHOW SLAVE STATUS` returns the following fields:

- `Slave_IO_State`

  A copy of the `State` field of the output of `SHOW PROCESSLIST` for the slave I/O thread. This tells you if the thread is trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. Possible states are listed in Section 6.4, “Replication Implementation Details”. Looking at this field is necessary for older versions of MySQL which allowed the thread to continue running while unsuccessfully trying to connect to the master. If it is running, there is no problem; if it is not, you can find the error in the `Last_Error` field (described below).

- `Master_Host`

  The current master host.

- `Master_User`

  The current user used to connect to the master.

- `Master_Port`

  The current master port.

- `Connect_Retry`

  The current value of the `--master-connect-retry` option.

- `Master_Log_File`

  The name of the master binary log file from which the I/O thread is currently reading.

- `Read_Master_Log_Pos`

  The position up to which the I/O thread has read in the current master binary log.

- `Relay_Log_File`

  The name of the relay log file from which the SQL thread is currently reading and executing.

- `Relay_Log_Pos`

  The position up to which the SQL thread has read and executed in the current relay log.

- `Relay_Master_Log_File`

  The name of the master binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

  Whether or not the I/O thread is started and has connected successfully to the master. For older versions of MySQL (prior to 4.1.14 and 5.0.12) `Slave_IO_Running` will be set to `YES` if the I/O thread is started, even if the slave hasn't connected to the master yet.

- `Slave_SQL_Running`

  Whether or not the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

  The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

  The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore_table` options, if any.

- `Last_Errno`, `Last_Error`

  The error number and error message returned by the most recently executed query. An error number of 0 and message of the empty string mean “no error.” If the `Last_Error` value is not empty, it also appears as a message in the slave's error log.

  For example:

  ```
  Last_Errno: 1051
  Last_Error: error 'Unknown table 'z'' on query 'drop table z'
  ```

  The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

- `Skip_Counter`

  The most recently used value for `SQL_SLAVE_SKIP_COUNTER`.

- `Exec_Master_Log_Pos`

  The position of the last event executed by the SQL thread from the master's binary log (`Relay_Master_Log_File`). (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log corresponds to (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

  The total combined size of all existing relay logs.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

  The values specified in the `UNTIL` clause of the `START SLAVE` statement.

  `Until_Condition` has these values:

  - `None` if no `UNTIL` clause was specified
  - `Master` if the slave is reading until a given position in the master's binary logs
  - `Relay` if the slave is reading until a given position in its relay logs

`Until_Log_File` and `Until_Log_Pos` indicate the log filename and position values that define the point at which the SQL thread stops executing.

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_Key`

  These fields show the SSL parameters used by the slave to connect to the master, if any.

  `Master_SSL_Allowed` has these values:

  - `Yes` if an SSL connection to the master is permitted
  - `No` if an SSL connection to the master is not permitted
  - `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

  The values of the other SSL-related fields correspond to the values of the `--master-ca`, `--master-capath`, `--master-cert`, `--master-cipher`, and `--master-key` options.

- `Seconds_Behind_Master`

  This field is an indication of how “late” the slave is. When the slave SQL thread is actively running (processing updates), this field is the number of seconds that have elapsed since the timestamp of the most recent event on the master executed by that thread. When that thread has caught up on the slave I/O thread and goes idle waiting for more events from the I/O thread this field is zero. In sum, this field measures in seconds the time difference between the slave SQL thread and the slave I/O thread.

  If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is **not** a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, **this column is useful only for fast networks**.

  This time difference computation works even though the master and slave do not have identical clocks (the clock difference is computed when the slave I/O thread starts, and assumed to remain constant from then on). `Seconds_Behind_Master` is `NULL` (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. For example if the slave I/O thread is sleeping for `master-connect-retry` seconds before reconnecting, `NULL` is shown, as the slave cannot know what the master is doing, and so cannot say reliably how late it is.

  This field has one limitation. The timestamp is preserved through replication, which means that, if a master M1 is itself a slave of M0, any event from M1's binlog which originates in replicating an event from M0's binlog has the timestamp of that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the drawback for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, then the value randomly deviates, because sometimes the last M1's event is from M0 and sometimes it is from a direct update, and so is the most recent timestamp.

13.6.2.8. START SLAVE Syntax

```
START SLAVE [thread_type [, thread_type] ... ]
START SLAVE [SQL_THREAD] UNTIL
    MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START SLAVE [SQL_THREAD] UNTIL
    RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos

thread_type: IO_THREAD | SQL_THREAD
```

START SLAVE with no options starts both of the slave threads. The I/O thread reads queries from the master server and stores them in the relay log. The SQL thread reads the relay log and executes the queries. START SLAVE requires the SUPER privilege.

If START SLAVE succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary logs, or some other problem). START SLAVE does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with SHOW SLAVE STATUS.

You can add IO_THREAD and SQL_THREAD options to the statement to name which of the threads to start.

An UNTIL clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary logs or in the slave relay logs. When the SQL thread reaches that point, it stops. If the SQL_THREAD option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the UNTIL clause is ignored and a warning is issued.

For an UNTIL clause, you must specify both a log filename and position. Do not mix master and relay log options.

Any UNTIL condition is reset by a subsequent STOP SLAVE statement, a START SLAVE statement that includes no UNTIL clause, or a server restart.

The UNTIL clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate a statement. For example, if an unwise DROP TABLE statement was executed on the master, you can use UNTIL to tell the slave to execute up to that point but no farther. To find what the event is, use mysqlbinlog with the master logs or slave relay logs, or by using a SHOW BINLOG EVENTS statement.

If you are using UNTIL to have the slave process replicated queries in sections, it is recommended that you start the slave with the --skip-slave-start option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The SHOW SLAVE STATUS statement includes output fields that display the current values of the UNTIL condition.

In previous versions of MySQL, this statement was called SLAVE START. This usage is still accepted in MySQL 5.1 for backward compatibility, but is now deprecated.

13.6.2.9. STOP SLAVE Syntax

```
STOP SLAVE [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. STOP SLAVE requires the SUPER privilege.

Like START SLAVE, this statement may be used with the IO_THREAD and SQL_THREAD options to name the thread or threads to be stopped.

In previous versions of MySQL, this statement was called SLAVE STOP. This usage is still accepted in MySQL 5.1 for backward compatibility, but is now deprecated.

13.7. SQL Syntax for Prepared Statements

MySQL 5.1 provides support for server-side prepared statements. This support takes advantage of

the efficient client/server binary protocol implemented in MySQL 4.1, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See Section 25.2.4, “C API Prepared Statements”. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the mysqli extension in PHP 5.0 [http://php.net/mysqli].

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that allows you to send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You may want to test how prepared statements work in your application before coding it, or perhaps an application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

```
PREPARE stmt_name FROM preparable_stmt;

EXECUTE stmt_name [USING @var_name [, @var_name] ...];

{DEALLOCATE | DROP} PREPARE stmt_name;
```

The `PREPARE` statement prepares a statement and assigns it a name, *`stmt_name`*, by which to refer to the statement later. Statement names are not case sensitive. *`preparable_stmt`* is either a string literal or a user variable that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, ‘`?`’ characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The ‘`?`’ characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with that name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the client session within which it is created. Other clients cannot see it.

After preparing a statement, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `US-`

ING clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the USING clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

To deallocate a prepared statement, use the DEALLOCATE PREPARE statement. Attempting to execute a prepared statement after deallocating it results in an error.

If you terminate a client session without deallocating a previously prepared statement, the server deallocates it automatically.

The following SQL statements can be used in prepared statements: CREATE TABLE, DELETE, DO, INSERT, REPLACE, SELECT, SET, UPDATE, and most SHOW statements. Other statements are not yet supported.

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|          5 |
+------------+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|         10 |
+------------+
mysql> DEALLOCATE PREPARE stmt2;
```

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to PREPARE cannot itself be a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the mysql_stmt_prepare() C API function to prepare a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

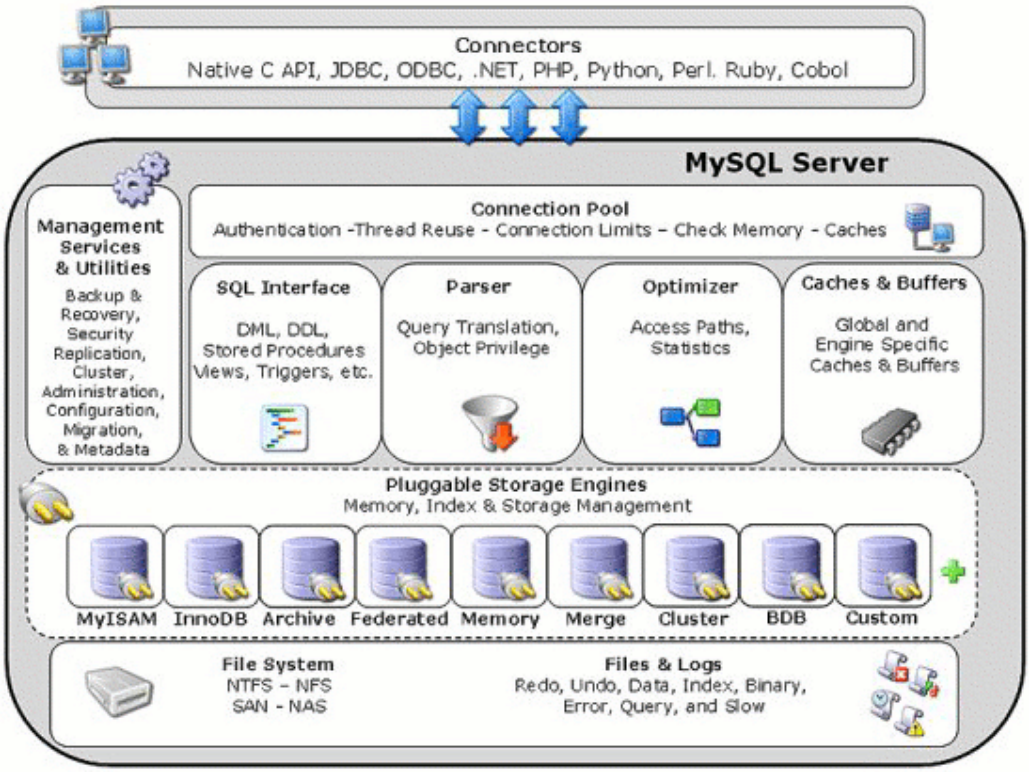
SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers.

Placeholders can be used in the LIMIT clause when using prepared statements. See Section 13.2.7, “SELECT Syntax”.

Chapter 14. Pluggable Storage Engine Architecture

14.1. Introduction to Pluggable Storage Engine Support

With MySQL 5.1, MySQL AB has introduced a new pluggable storage engine architecture that allows storage engines to be loaded into a running MySQL server.



This chapter describes the pluggable storage engine architecture and provides an overview of the various storage engines provided with MySQL along with instructions on how to assign storage engines to tables and plug and unplug storage engines.

14.2. Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture allows a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level providing a consistent and easy application model and API. So while there are different capabilities across different storage engines, the application is shielded from these.

Graphically depicted, the MySQL pluggable storage engine architecture looks like the following:

Figure 14.1. The MySQL pluggable storage engine architecture

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need – such as data warehousing, transaction processing, high availability situations, etc. – while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more additional storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy to use API that applies across storage engines.

14.3. The Common MySQL Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key differentiations include:

- `Concurrency` – some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore help with overall performance. This area also includes support for capabilities like multi-version concurrency control or “snapshot” read.
- `Transaction Support` – not every application needs transactions, but for those that do, there are very well defined requirements like ACID compliance and more.
- `Referential Integrity` – the need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- `Physical Storage` – this involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- `Index Support` – different application scenarios tend to benefit from different index strategies, and so each storage engine generally has its own indexing methods, although some (like B-tree indexes) are common to nearly all engines.
- `Memory Caches` – different applications respond better to some memory caching strategies than others, so while some memory caches are common to all storage engines (like those used for user connections, MySQL’s high-speed Query Cache, etc.), others are uniquely defined only when a particular storage engine is put in play.
- `Performance Aids` – includes things like multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- `Miscellaneous Target Features` – this may include things like support for geospatial

operations, security restrictions for certain data manipulation operations, and other like items.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps steer clear of unnecessary overhead. So it stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

14.4. Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use-cases in mind. In order to use the pluggable storage architecture effectively, it is good to have an idea of the benefits and drawbacks of the various storage engines.

The following table provides an overview of the storage engines provided with MySQL:

Figure 14.2. Storage engine comparison

Feature	MyISAM	BDB	Memory	InnoDB	Archive	NDB
Storage Limits	No	No	Yes	64TB	No	Yes
Transactions (commit, rollback, etc.)		✔		✔		
Locking granularity	Table	Page	Table	Row	Row	Row
MVCC/Snapshot Read				✔	✔	✔
Geospatial support	✔					
B-Tree indexes	✔	✔	✔	✔		✔
Hash indexes			✔	✔		✔
Full text search index	✔					
Clustered index				✔		
Data Caches			✔	✔		✔
Index Caches	✔		✔	✔		✔
Compressed data	✔				✔	
Encrypted data (via function)	✔	✔	✔	✔	✔	✔
Storage cost (space used)	Low	Low	N/A	High	Very Low	Low
Memory cost	Low	Low	Medium	High	Low	High
Bulk Insert Speed	High	High	High	Low	Very High	High
Cluster database support						✔
Replication support	✔	✔	✔	✔	✔	✔
Foreign key support				✔		
Backup/Point-in-time recovery	✔	✔	✔	✔	✔	✔
Query cache support	✔	✔	✔	✔	✔	✔
Update Statistics for Data Dictionary	✔	✔	✔	✔	✔	✔

The following storage engines are the most commonly used:

- `MyISAM` - the default MySQL pluggable storage engine and the one that is used the most in Web, data warehousing, and other application environments. Note that a MySQL server's default storage engine can easily be changed by altering the STORAGE_ENGINE configuration variable.
- `InnoDB` - used for transaction processing applications, and sports a number of features including ACID transaction support.
- `BDB` - an alternative transaction engine to `InnoDB` that supports `COMMIT`, `ROLLBACK`, and other transactional features.

- `Memory` - stores all data in RAM for extremely fast access in environments that require quick look ups of reference and other like data.
- `Merge` - allows a MySQL DBA or developer to logically group together a series of identical `MyISAM` tables and reference them as one object. Good for VLDB environments like data warehousing.
- `Archive` - provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- `Federated` - offers the ability to link together separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- `NDB` - the Clustered database engine of MySQL that is particularly suited for applications with high performance lookup needs that also require the highest possible degree of uptime and availability.
- `Other` - other storage engines include CSV (references comma-separated files as database tables), Blackhole (for temporarily disabling application input to the database) and an Example engine that helps jump start the process of creating custom pluggable storage engines.

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

For detailed information on the storage engines included with MySQL, see Section 14.4, “Choosing a Storage Engine”.

14.5. Assigning Storage Engines to Tables

Storage engines can be designated either when creating new tables or through the use of an `ALTER TABLE` statement.

To specify a storage engine when creating a table, use the `ENGINE` parameter:

```
CREATE TABLE engineTest(
id INT
) ENGINE = MyISAM;
```

To change the storage engine of an existing table, use the `ALTER TABLE` statement:

```
ALTER TABLE engineTest ENGINE = ARCHIVE;
```

14.6. Storage Engines and Transactions

Transactions are supported by the following storage engines:

- `InnoDB` - Supports transactions through MVCC, allows for `COMMIT`, `ROLLBACK`, and savepoints.
- `NDB` - Supports transactions, allows for `COMMIT` and `ROLLBACK`.
- `BDB` - Supports transactions, allows for `COMMIT` and `ROLLBACK`.

14.7. Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin must be loaded into mysql using the

`INSTALL PLUGIN` statement. For example, to load the example engine you would first load the ha_example.so module:

```
INSTALL PLUGIN ha_example SONAME 'ha_example.so';
```

The `.so` file must be located in the MySQL server library directory (typically `installdir/lib`).

14.8. Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN ha_example;
```

If you unplug a storage engine that is being used by existing tables, those tables will not be accessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

14.9. Security Implications of Pluggable Storage

In order to install a pluggable storage engine, the plugin file must be located in the appropriate MySQL library directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privileges on the `mysql.plugin` table.

Chapter 15. Storage Engines and Table Types

MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle non-transaction-safe tables:

- `MyISAM` manages non-transactional tables. It provides high-speed storage and retrieval, as well as fulltext searching capabilities. `MyISAM` is supported in all MySQL configurations, and is the default storage engine unless you have configured MySQL to use a different one by default.
- The `MEMORY` storage engine provides in-memory tables. The `MERGE` storage engine allows a collection of identical `MyISAM` tables to be handled as a single table. Like `MyISAM`, the `MEMORY` and `MERGE` storage engines handle non-transactional tables, and both are also included in MySQL by default.

  Note: The `MEMORY` storage engine was formerly known as the `HEAP` engine.
- The `InnoDB` and `BDB` storage engines provide transaction-safe tables. `BDB` is included in MySQL-Max binary distributions on those operating systems that support it. `InnoDB` is also included by default in all MySQL 5.1 binary distributions. In source distributions, you can enable or disable either engine by configuring MySQL as you like.
- The `EXAMPLE` storage engine is a "stub" engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.
- `NDB Cluster` is the storage engine used by MySQL Cluster to implement tables that are partitioned over many computers. It is available in MySQL-Max 5.1 binary distributions. This storage engine is currently supported on Linux, Solaris, and Mac OS X only. We intend to add support for this engine on other platforms, including Windows, in future MySQL releases.
- The `ARCHIVE` storage engine is used for storing large amounts of data without indexes with a very small footprint.
- The `CSV` storage engine stores data in text files using comma-separated-values format.
- The `BLACKHOLE` storage engine accepts but does not store data and retrievals always return an empty set.
- The `FEDERATED` storage engine stores data in a remote database. In MySQL 5.1, it works with MySQL only, using the MySQL C Client API. In future releases, we intend to enable it to connect to other data sources using other drivers or client connection methods.

For assistance in choosing a storage engine, see Section 14.4, "Choosing a Storage Engine".

This chapter describes each of the MySQL storage engines except for `NDB Cluster`, which is covered in Chapter 17, *MySQL Cluster*.

When you create a new table, you can tell MySQL what type of table to create by adding an `ENGINE` or `TYPE` table option to the `CREATE TABLE` statement:

```
CREATE TABLE t (i INT) ENGINE = INNODB;
CREATE TABLE t (i INT) TYPE = MEMORY;
```

Although `TYPE` is still supported in MySQL 5.1, `ENGINE` is now the preferred term.

If you omit the ENGINE or TYPE option, the default storage engine is used. Normally this is MyISAM, but you can change it by using the --default-storage-engine or --default-table-type server startup option, or by setting the storage_engine or table_type system variable.

When MySQL is installed on Windows using the MySQL Configuration Wizard, the InnoDB storage engine is the default instead of MyISAM. See Section 2.3.5.1, “Introduction to the Configuration Wizard”.

To convert a table from one type to another, use an ALTER TABLE statement that indicates the new type:

```
ALTER TABLE t ENGINE = MYISAM;
ALTER TABLE t TYPE = BDB;
```

See Section 13.1.5, “CREATE TABLE Syntax”, and Section 13.1.2, “ALTER TABLE Syntax”.

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table of type MyISAM. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only non-transactional storage engines for greater speed.)

This automatic substitution of the MyISAM storage engine when an unavailable engine is specified can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed.

MySQL always creates an .frm file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the .frm file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage.

A database may contain tables of different types.

Transaction-safe tables (TSTs) have several advantages over non-transaction-safe tables (NTSTs):

- They are safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.
- You can combine many statements and accept them all at the same time with the COMMIT statement (if autocommit is disabled).
- You can execute ROLLBACK to ignore your changes (if autocommit is disabled).
- If an update fails, all of your changes are reverted. (With non-transaction-safe tables, all changes that have taken place are permanent.)
- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

Although MySQL supports several transaction-safe storage engines, for best results, you should not mix different storage engines within a transaction. For information about the problems that can occur if you do this, see Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

InnoDB uses default configuration values if you specify none. See Section 15.2.3, “InnoDB Configuration”.

Non-transaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster
- Lower disk space requirements
- Less memory required to perform updates

You can combine transaction-safe and non-transaction-safe tables in the same statements to get the best of both worlds. However, within a transaction with autocommit disabled, changes to non-transaction-safe tables still are committed immediately and cannot be rolled back.

15.1. The MyISAM Storage Engine

MyISAM is the default storage engine. It is based on the older ISAM code but has many useful extensions. (Note that MySQL 5.1 does *not* support ISAM.)

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table definition. The data file has an .MYD (MYData) extension. The index file has an .MYI (MYIndex) extension.

To specify explicitly that you want a MyISAM table, indicate that with an ENGINE table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

(**Note**: Older versions of MySQL used TYPE rather than ENGINE (for example: TYPE = MYISAM). MySQL 5.1 supports this syntax for backward compatibility but TYPE is now deprecated and ENGINE is the preferred usage.)

Normally, the ENGINE option is unnecessary; MyISAM is the default storage engine unless the default has been changed.

You can check or repair MyISAM tables with the myisamchk utility. See Section 5.9.5.6, “Using myisamchk for Crash Recovery”. You can also compress MyISAM tables with myisampack to take up much less space. See Section 8.2, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

The following are some characteristics of the MyISAM storage engine:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirement for binary portability is that the machine uses two's-complement signed integers (as every machine for the last 20 years has) and IEEE floating-point format (also totally dominant among mainstream machines). The only area of machines that may not support binary compatibility are embedded systems, which sometimes have peculiar processors.

  There is no big speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it doesn't take that much more power to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- Large files (up to 63-bit file length) are supported on filesystems and operating systems that support large files.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.

- The maximum number of indexes per MyISAM table is 64. This can be changed by recompiling; beginning with MySQL 5.1.4, you can configure the build using the --with-max-indexes=*N*, where *N*#128 is the maximum number of indexes to permit per MyISAM table.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are allowed in indexed columns. This takes 0-1 bytes per key.
- All numeric key values are stored with the high byte first to allow better index compression.
- When records are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table. `MyISAM` automatically updates this column for `INSERT`and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.
- If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. (These are known as concurrent inserts.) A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again.
- You can put the data file and index file on different directories to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See Section 13.1.5, “`CREATE TABLE` Syntax”.
- Each character column can have a different character set. See Chapter 10, *Character Set Support*.
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in two bytes.
- Tables with `VARCHAR` may have fixed or dynamic record length.
- `VARCHAR` and `CHAR` columns may be up to 64KB.
- A hashed computed index can be used for `UNIQUE`. This allows you to have `UNIQUE` on any combination of columns in a table. (However, you cannot search on a `UNIQUE` computed index.)

Additional resources

- For the MyISAM storage engine, there's a dedicated forum available on http://forums.mysql.com/list.php?21.

15.1.1. MyISAM Startup Options

The following options to mysqld can be used to change the behavior of MyISAM tables:

- --myisam-recover=*mode*

  Set the mode for automatic recovery of crashed MyISAM tables.

- --delay-key-write=ALL

  Don't flush key buffers between writes for any MyISAM table.

  Note: If you do this, you should not use MyISAM tables from another program (such as from another MySQL server or with myisamchk) when the table is in use. Doing so leads to index corruption.

  Using --external-locking does not help for tables that use --delay-key-write.

See Section 5.3.1, "mysqld Command-Line Options".

The following system variables affect the behavior of MyISAM tables:

- bulk_insert_buffer_size

  The size of the tree cache used in bulk insert optimization. **Note**: This is a limit *per thread*!

- (*OBSOLETE*) myisam_max_extra_sort_file_size

  This parameter is no longer used in MySQL.

- myisam_max_sort_file_size

  Don't use the fast sort index method to create an index if the temporary file would become larger than this. **Note**: This parameter is given in bytes.

- myisam_sort_buffer_size

  Set the size of the buffer used when recovering tables.

See Section 5.3.3, "Server System Variables".

Automatic recovery is activated if you start mysqld with the --myisam-recover option. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with --skip-external-locking. If either of these conditions is true, the following happens:

- The table is checked for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by

row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from a previous completed statement and you didn't specify FORCE in the value of the --myisam-recover option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify FORCE, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes BACKUP, the recovery process creates files with names of the form *tbl_name-datetime*.BAK. You should have a cron script that automatically moves these files from the database directories to backup media.

15.1.2. Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as (key_length+4)/0.67, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if the string column has a lot of trailing space or is a VARCHAR column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying PACK_KEYS=1 when you create the table. This helps when you have many integer keys that have an identical prefix when the numbers are stored high-byte first.

15.1.3. MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them (fixed and dynamic format) are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the myisampack utility.

When you CREATE or ALTER a table that has no BLOB or TEXT columns, you can force the table format to FIXED or DYNAMIC with the ROW_FORMAT table option. This causes CHAR and VARCHAR columns to become CHAR for FIXED format, or VARCHAR for DYNAMIC format.

You can compress or decompress tables by specifying ROW_FORMAT={COMPRESSED | DEFAULT} with ALTER TABLE. See Section 13.1.5, “CREATE TABLE Syntax”.

15.1.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (VARCHAR, BLOB, or TEXT). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats. The speed comes from the easy way that rows in the data file can be found on disk: When looking up a row based on a row number in the index, multiply the row number by the row length. Also, when scanning a table, it is very easy to read a constant number of records with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, myisamchk can easily determine where each row starts and

ends, so it can usually reclaim all records except the partially written one. Note that MyISAM table indexes can always be reconstructed based on the data rows.

General characteristics of static format tables:

- CHAR columns are space-padded to the column width.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because records are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of records and want to return free disk space to the operating system. To do this, use OPTIMIZE TABLE or myisamchk -r.
- Usually require more disk space than for dynamic-format tables.

15.1.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (VARCHAR, BLOB, or TEXT), or if the table was created with the ROW_FORMAT=DYNAMIC option.

This format is a little more complex because each row has a header that indicates how long it is. One record can also end up at more than one location when it is made longer as a result of an update.

You can use OPTIMIZE TABLE or myisamchk to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

General characteristics of dynamic-format tables:

- All string columns are dynamic except those with a length less than four.
- Each record is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain NULL values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Non-empty strings are saved as a length byte plus the string contents.
- Much less disk space usually is required than for fixed-length tables.
- Each record uses only as much space as is required. However, if a record becomes larger, it is split into as many pieces as are required, resulting in record fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run OPTIMIZE TABLE or myisamchk -r from time to time to improve performance. Use myisamchk -ei to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because a record may be fragmented into many pieces and a link (fragment) may be missing.
- The expected row length for dynamic-sized records is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic record is linked whenever an update causes an enlargement of the record. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `myisamchk -r`.

15.1.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool.

All MySQL distributions include `myisampack` by default. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each record is compressed separately, so there is very little access overhead. The header for a record takes up 1 to 3 bytes depending on the biggest record in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can handle fixed-length or dynamic-length records.

15.1.4. `MyISAM` Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted.

15.1.4.1. Corrupted `MyISAM` Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- Unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) on a table that is being modified by the server at the same time.

- A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

  ```
  Incorrect key file for table: '...'. Try to repair it
  ```

- Queries don't find rows in the table or return incomplete data.

You can check the health of a MyISAM table using the CHECK TABLE statement, and repair a corrupted MyISAM table with REPAIR TABLE. When mysqld is not running, you can also check or repair a table with the myisamchk command. See Section 13.5.2.3, "CHECK TABLE Syntax", Section 13.5.2.6, "REPAIR TABLE Syntax", and Section 5.9.5, "myisamchk — MyISAM Table-Maintenance Utility".

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent restarted mysqld message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section A.4.2, "What to Do If MySQL Keeps Crashing", and Section E.1.6, "Making a Test Case If You Experience Table Corruption".

15.1.4.2. Problems from Tables Not Being Closed Properly

Each MyISAM index (.MYI) file has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from CHECK TABLE or myisamchk, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because of a FLUSH TABLES operation or because there isn't room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can go out of sync only under these conditions:

- The MyISAM tables are copied without first issuing LOCK TABLES and FLUSH TABLES.

- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not signaled to the other servers.

  In general, it is a bad idea to share a data directory among multiple servers. See Section 5.12, “Running Multiple MySQL Servers on the Same Machine”, for additional discussion.

15.2. The InnoDB Storage Engine

15.2.1. InnoDB Overview

`InnoDB` provides MySQL with a transaction-safe (`ACID` compliant) storage engine that has commit, rollback, and crash recovery capabilities. `InnoDB` does locking on the row level and also provides an Oracle-style consistent non-locking read in `SELECT` statements. These features increase multi-user concurrency and performance. There is no need for lock escalation in `InnoDB` because row-level locks fit in very little space. `InnoDB` also supports `FOREIGN KEY` constraints. You can freely mix `InnoDB` tables with tables from other MySQL storage engines, even within the same statement.

`InnoDB` has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

Fully integrated with MySQL Server, the `InnoDB` storage engine maintains its own buffer pool for caching data and indexes in main memory. `InnoDB` stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, `MyISAM` tables where each table is stored using separate files. `InnoDB` tables can be of any size even on operating systems where file size is limited to 2GB.

`InnoDB` is included in binary distributions by default. The Windows Essentials installer makes `InnoDB` the MySQL default storage engine on Windows.

`InnoDB` is used in production at numerous large database sites requiring high performance. The famous Internet news site Slashdot.org runs on `InnoDB`. Mytrix, Inc. stores over 1TB of data in `InnoDB`, and another site handles an average load of 800 inserts/updates per second in `InnoDB`.

`InnoDB` is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

Additional resources

- A forum dedicated to the `InnoDB` storage engine is available at http://forums.mysql.com/list.php?22.

15.2.2. InnoDB Contact Information

Contact information for Innobase Oy, producer of the `InnoDB` engine:

```
Web site: http://www.innodb.com/
Email: <sales@innodb.com>
Phone: +358-9-6969 3250 (office)
```

```
       +358-40-5617367 (mobile)

Innobase Oy Inc.
World Trade Center Helsinki
Aleksanterinkatu 17
P.O.Box 800
00101 Helsinki
Finland
```

15.2.3. InnoDB Configuration

The InnoDB storage engine is enabled by default. If you don't want to use InnoDB tables, you can add the skip-innodb option to your MySQL option file.

Note: InnoDB provides MySQL with a transaction-safe (ACID compliant) storage engine that has commit, rollback, and crash recovery capabilities. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations in order to improve performance. On some operating systems, the very system call that should wait until all unwritten data for a file has been flushed — fsync() — might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, you should perform some "pull-the-plug" tests before using anything in production. On Mac OS X 10.3 and up, InnoDB uses a special fcntl() file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATAPI hard disks, a command such hdparm -W0 /dev/hda may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

Two important disk-based resources managed by the InnoDB storage engine are its tablespace data files and its log files.

Note: If you specify no InnoDB configuration options, MySQL creates an auto-extending 10MB data file named ibdata1 and two 5MB log files named ib_logfile0 and ib_logfile1 in the MySQL data directory. To get good performance, you should explicitly provide InnoDB parameters as discussed in the following examples. Naturally, you should edit the settings to suit your hardware and requirements.

The examples shown here are representative. See Section 15.2.4, "InnoDB Startup Options and System Variables" for additional information about InnoDB-related configuration parameters.

To set up the InnoDB tablespace files, use the innodb_data_file_path option in the [mysqld] section of the my.cnf option file. On Windows, you can use my.ini instead. The value of innodb_data_file_path should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (';') characters:

```
innodb_data_file_path=datafile_spec1[;datafile_spec2]...
```

For example, a setting that explicitly creates a tablespace having the same characteristics as the default is as follows:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
```

This setting configures a single 10MB data file named ibdata1 that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using M or G suffix letters to indicate units of MB or GB.

A tablespace containing a fixed-size 50MB data file named ibdata1 and a 50MB auto-extending file named ibdata2 in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the filename, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` attribute and those following can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, `InnoDB` extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. It can be modified by changing the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. Instructions for reconfiguring an existing tablespace are given in Section 15.2.7, “Adding and Removing `InnoDB` Data and Log Files”.

`InnoDB` is not aware of the filesystem maximum file size, so be cautious on filesystems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute. The following configuration allows `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend:max:500M
```

`InnoDB` creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure `InnoDB` like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note: `InnoDB` does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

`InnoDB` forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a pathname separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not mentioned in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

A simple `my.cnf` example. Suppose that you have a computer with 128MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for `InnoDB`, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute `InnoDB` data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two `InnoDB` log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Also, the small archived `InnoDB` log file

`ib_arch_log_0000000000` that `InnoDB` creates automatically ends up in the data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=70M
innodb_additional_mem_pool_size=10M
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=20M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

Note that data files must be less than 2GB in some filesystems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least 10MB.

When you create an `InnoDB` tablespace for the first time, it is best that you start the MySQL server from the command prompt. `InnoDB` then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld-max` is located in `C:\Program Files\MySQL\MySQL Server 5.1\bin`, you can start it like this:

```
C:\> C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld-max --console
```

If you do not send server output to the screen, check the server's error log to see what `InnoDB` prints during the startup process.

See Section 15.2.5, “Creating the `InnoDB` Tablespace”, for an example of what the information displayed by `InnoDB` should look like.

You can place `InnoDB` options in the `[mysqld]` group of any option file that your server reads when it starts. The locations for option files are described in Section 4.3.2, “Using Option Files”.

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the `my.ini` file located in your MySQL installation directory. See Section 2.3.5.14, “The Location of the my.ini File”.

If your PC uses a boot loader where the `C:` drive is not the boot drive, your only option is to use the `my.ini` file in your Windows directory (typically `C:\WINDOWS` or `C:\WINNT`). You can use the `SET` command at the command prompt in a console window to print the value of `WINDIR`:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

If you want to make sure that `mysqld` reads options only from a specific file, you can use the `--defaults-option` as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my_cnf
```

An advanced `my.cnf` example. Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths `/`, `/dr2` and `/dr3`. The following example shows possible configuration parameters in `my.cnf` for `InnoDB`.

```
[mysqld]
```

```
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
innodb_data_file_path = /ibdata/ibdata1:2000M;/dr2/ibdata/ibdata2:2000M:autoext
#
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
#
innodb_log_files_in_group = 2
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
#
# Uncomment the next lines if you want to use them
#innodb_thread_concurrency=5
```

In some cases, database performance improves the if all data is not placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. `InnoDB` fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as `InnoDB` data files, which may speed up I/O. See Section 15.2.3.2, “Using Raw Devices for the Shared Tablespace”.

Warning: On 32-bit GNU/Linux x86, you must be careful not to set memory usage too high. `glibc` may allow the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL AB binaries) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

By compiling MySQL yourself, you can use up to 64GB of physical memory in 32-bit Windows. See the description for `innodb_buffer_pool_awe_mem_mb` in Section 15.2.4, “`InnoDB` Startup Options and System Variables”.

How to tune other `mysqld` server parameters? The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=value
```

15.2.3.1. Using Per-Table Tablespaces

You can store each InnoDB table and its indexes in its own file. This feature is called “multiple tablespaces” because in effect each table has its own tablespace.

Using multiple tablespaces can be beneficial to users who want to move specific tables to separate physical disks or who wish to restore backups of single tables quickly without interrupting the use of the remaining InnoDB tables.

You can enable multiple tablespaces by adding this line to the [mysqld] section of my.cnf:

```
[mysqld]
innodb_file_per_table
```

After restarting the server, InnoDB stores each newly created table into its own file *tbl_name*.ibd in the database directory where the table belongs. This is similar to what the MyISAM storage engine does, but MyISAM divides the table into a data file *tbl_name*.MYD and the index file *tbl_name*.MYI. For InnoDB, the data and the indexes are stored together in the .ibd file. The *tbl_name*.frm file is still created as usual.

If you remove the innodb_file_per_table line from my.cnf and restart the server, InnoDB creates tables inside the shared tablespace files again.

innodb_file_per_table affects only table creation. If you start the server with this option, new tables are created using .ibd files, but you can still access tables that exist in the shared tablespace. If you remove the option, new tables are created in the shared tablespace, but you can still access any tables that were created using multiple tablespaces.

InnoDB always needs the shared tablespace. The .ibd files are not sufficient for InnoDB to operate. The shared tablespace consists of the familiar ibdata files where InnoDB puts its internal data dictionary and undo logs.

Note: You cannot freely move .ibd files between database directories as you can with MyISAM table files. This is because the table definition is stored in the InnoDB shared tablespace, and because InnoDB must preserve the consistency of transaction IDs and log sequence numbers.

Within a given MySQL installation, you can move an .ibd file and the associated table from one database to another with a RENAME TABLE statement:

```
RENAME TABLE old_db_name.tbl_name TO new_db_name.tbl_name;
```

If you have a “clean” backup of an .ibd file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this ALTER TABLE statement:

   ```
   ALTER TABLE tbl_name DISCARD TABLESPACE;
   ```

   Caution: This statement deletes the current .ibd file.

2. Put the backup .ibd file back in the proper database directory.

3. Issue this ALTER TABLE statement:

   ```
   ALTER TABLE tbl_name IMPORT TABLESPACE;
   ```

In this context, a “clean” .ibd file backup means:

- There are no uncommitted modifications by transactions in the .ibd file.

- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of `InnoDB` is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the commercial `InnoDB Hot Backup` tool:

1. Use `InnoDB Hot Backup` to back up the `InnoDB` installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

15.2.3.2. Using Raw Devices for the Shared Tablespace

You can also use raw disk partitions as data files in the shared tablespace. By using a raw disk, you can perform non-buffered I/O on Windows and on some Unix systems without filesystem overhead, which may improve performance.

When you create a new data file, you must put the keyword `newraw` immediately after the data file size in `innodb_data_file_path`. The partition must be at least as large as the size that you specify. Note that 1MB in `InnoDB` is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
```

The next time you start the server, `InnoDB` notices the `newraw` keyword and initializes the new partition. However, do not create or change any `InnoDB` tables yet. Otherwise, when you next restart the server, `InnoDB` reinitializes the partition and your changes are lost. (As a safety measure `InnoDB` prevents users from modifying data when any partition with `newraw` is specified.)

After `InnoDB` has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:5Graw;/dev/hdd2:2Graw
```

Then restart the server and `InnoDB` allows changes to be made.

On Windows, you can allocate a disk partition as a data file like this:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives.

When you use raw disk partitions, be sure that they have permissions that allow read and write access by the account used for running the MySQL server.

15.2.4. InnoDB Startup Options and System Variables

This section describes the InnoDB-related server options, all of which can be specified in *--opt_name=value* form on the command line or in option files.

- innodb_additional_mem_pool_size

  The size of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system, and writes warning messages to the MySQL error log. The default value is 1MB.

- innodb_autoextend_increment

  The increment size (in megabytes) for extending the size of an auto-extending tablespace when it becomes full. The default value is 8. This option can be changed at runtime as a global system variable.

- innodb_buffer_pool_awe_mem_mb

  The size of the buffer pool (in MB), if it is placed in the AWE memory of 32-bit Windows. (Relevant only in 32-bit Windows.) If your 32-bit Windows operating system supports more than 4GB memory, using so-called "Address Windowing Extensions", you can allocate the InnoDB buffer pool into the AWE physical memory using this parameter. The maximum possible value for this is 64000. If this parameter is specified, innodb_buffer_pool_size is the window in the 32-bit address space of mysqld where InnoDB maps that AWE memory. A good value for innodb_buffer_pool_size is 500MB.

  To take advantage of AWE memory, you will need to recompile MySQL yourself. The current project settings needed for doing this can be found in the storage/innobase/os/os0proj.c source file.

- innodb_buffer_pool_size

  The size of the memory buffer InnoDB uses to cache data and indexes of its tables. The larger you set this value, the less disk I/O is needed to access data in tables. On a dedicated database server, you may set this to up to 80% of the machine physical memory size. However, do not set it too large because competition for the physical memory might cause paging in the operating system.

- innodb_checksums

  InnoDB uses checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded. In such cases, this option (which is enabled by default) can be turned off with --skip-innodb-checksums.

- innodb_commit_concurrency

  The number of threads that can commit at the same time. A value of 0 disables concurrency control.

- innodb_concurrency_tickets

  The number of threads that can enter InnoDB concurrently is determined by the innodb_thread_concurrency variable. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is allowed to enter InnoDB, it is given a number of "free tickets" equal to the value of in-

nodb_concurrency_tickets, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB.

- innodb_data_file_path

  The paths to individual data files and their sizes. The full directory path to each data file is acquired by concatenating innodb_data_home_dir to each path specified here. The file sizes are specified in megabytes or gigabytes (1024MB) by appending M or G to the size value. The sum of the sizes of the files must be at least 10MB. On some operating systems, files must be less than 2GB. If you do not specify innodb_data_file_path, the default behavior starting is to create a single 10MB auto-extending data file named ibdata1. You can set the file size to more than 4GB on those operating systems supporting big files. You can also use raw disk partitions as data files. See Section 15.2.3.2, “Using Raw Devices for the Shared Tablespace”.

- innodb_data_home_dir

  The common part of the directory path for all InnoDB data files. If you do not set this value, the default is the MySQL data directory. You can specify this also as an empty string, in which case you can use absolute file paths in innodb_data_file_path.

- innodb_doublewrite

  By default, InnoDB stores all data twice, first to the doublewrite buffer, and then to the actual data files. This option can be used to disable this functionality. Like innodb_checksums, this option is enabled by default; it can be turned off with --skip-innodb-doublewrite for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- innodb_fast_shutdown

  If you set this to 0, InnoDB does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If you set this parameter to 1, InnoDB skips these operations at shutdown. The default value is 1. If you set it to 2 (not available on Netware), InnoDB will just flush its logs and then shut down cold, as if MySQL had crashed; no committed transaction will be lost, but a crash recovery will be done at next startup.

- innodb_file_io_threads

  The number of file I/O threads in InnoDB. Normally this should be left at the default value of 4, but disk I/O on Windows may benefit from a larger number. On Unix, increasing the number has no effect; InnoDB always uses the default value.

- innodb_file_per_table

  This option causes InnoDB to create each new table using its own .ibd file for storing data and indexes, rather than in the shared tablespace. See Section 15.2.3.1, “Using Per-Table Tablespaces”.

- innodb_flush_log_at_trx_commit

  When innodb_flush_log_at_trx_commit is set to 0, once per second the log buffer is written out to the log file, and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When this value is 1 (the default), at each transaction commit the log buffer is written out to the log file, and the flush to disk operation is performed on the log file. When set to 2, at each commit the log buffer is written out to the file, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also in the case of 2. We must note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. You can achieve better performance by setting the value different from 1, but then you can lose at most one second worth of transactions in a crash. If you set the value to 0, then any mysqld process crash can erase the last second of transactions. If you set the value to 2, then only an operating system crash or a

power outage can erase the last second of transactions. However, InnoDB's crash recovery is not affected and thus crash recovery does work regardless of the value. Note that many operating systems and some disk hardware fool the flush-to-disk operation. They may tell mysqld that the flush has taken place, though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the InnoDB database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command hdparm to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor. The default value of this option is 1.

- innodb_flush_method

  If set to fdatasync (the default), InnoDB uses fsync() to flush both the data and log files. If set to O_DSYNC, InnoDB uses O_SYNC to open and flush the log files, but uses fsync() to flush the data files. If O_DIRECT is specified (available on some GNU/Linux versions), InnoDB uses O_DIRECT to open the data files, and uses fsync() to flush both the data and log files. Note that InnoDB uses fsync() instead of fdatasync(), and it does not use O_DSYNC by default because there have been problems with this on many varieties of Unix.

- innodb_force_recovery

  Warning: This option should be defined only in an emergency situation when you want to dump your tables from a corrupt database! Possible values are from 1 to 6. The meanings of these values are described in Section 15.2.8.1, “Forcing InnoDB Recovery”. As a safety measure, InnoDB prevents a user from modifying data when this option is greater than 0.

- innodb_lock_wait_timeout

  The timeout in seconds an InnoDB transaction may wait for a lock before being rolled back. InnoDB automatically detects transaction deadlocks in its own lock table and rolls back the transaction. InnoDB notices locks set using the LOCK TABLES statement. The default is 50 seconds.

  For the greatest possible durability and consistency in a replication setup you should use innodb_flush_log_at_trx_commit=1 and sync-binlog=1 in your master my.cnf file.

- innodb_locks_unsafe_for_binlog

  This option turns off next-key locking in InnoDB searches and index scans. Default value for this option is false.

  Normally InnoDB uses an algorithm called *next-key locking*. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on any index records it encounters. Thus, the row-level locks are actually index record locks. The locks that InnoDB sets on index records also affect the “gap” preceding that index record. If a user has a shared or exclusive lock on record *R* in an index, another user cannot insert a new index record immediately before *R* in the order of the index. This option causes InnoDB not to use next-key locking in searches or index scans. Next-key locking is still used to ensure foreign key constraints and duplicate key checking. Note that using this option may cause phantom problems: Suppose that you want to read and lock all children from the child table with an identifier value larger than 100, with the intention of updating some column in the selected rows later:

  ```
  SELECT * FROM child WHERE id > 100 FOR UPDATE;
  ```

  Suppose that there is an index on the id column. The query scans that index starting from the first record where id is greater than 100. If the locks set on the index records do not lock out inserts made in the gaps, a new row is meanwhile inserted into the table. If you execute the same SELECT within the same transaction, you see a new row in the result set returned by the query. This also means, that if new items are added to the database, InnoDB does not guarantee serializability; however, conflict serializability is still guaranteed. Therefore, if this option is used

InnoDB guarantees at most isolation level READ COMMITTED.

This option is even more unsafe. InnoDB in an UPDATE or a DELETE only locks rows that it updates or deletes. This greatly reduces the probability of deadlocks but they can happen. Note that this option still does not allow operations such as UPDATE to overtake like operations (such as another UPDATE) even in the case when they affect different rows. Consider the following example:

```
CREATE TABLE A(A INT NOT NULL, B INT);
INSERT INTO A VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

If one connection executes a query:

```
SET AUTOCOMMIT = 0;
UPDATE A SET B = 5 WHERE B = 3;
```

and the other connection executes, following the first one, another query:

```
SET AUTOCOMMIT = 0;
UPDATE A SET B = 4 WHERE B = 2;
```

Then query two has to wait for a commit or rollback of query one, because query one has an exclusive lock to row (2,3), and query two while scanning rows also tries to take an exclusive lock to the same row (2,3), which it cannot have. This is because query two first takes an exclusive lock on a row and then determines whether this row belongs to the result set, and if not then releases the unnecessary lock, when the option innodb_locks_unsafe_for_binlog is used.

Therefore, query one is executed as follows:

```
x-lock(1,2)
unlock(1,2)
x-lock(2,3)
update(2,3) to (2,5)
x-lock(3,2)
unlock(3,2)
x-lock(4,3)
update(4,3) to (4,5)
x-lock(5,2)
unlock(5,2)
```

and then query two is executed as follows:

```
x-lock(1,2)
update(1,2) to (1,4)
x-lock(2,3) - wait for query one to commit or rollback
```

- innodb_log_arch_dir

  The directory where fully written log files would be archived if we used log archiving. If used, the value of this parameter should be set the same as innodb_log_group_home_dir. However, it is not required.

- innodb_log_archive

  This value should currently be set to 0. Because recovery from a backup is done by MySQL using its own log files, there is currently no need to archive InnoDB log files. The default for this option is 0.

- innodb_log_buffer_size

The size of the buffer that `InnoDB` uses to write to the log files on disk. Sensible values range from 1MB to 8MB. The default is 1MB. A large log buffer allows large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

- `innodb_log_file_size`

  The size of each log file in a log group. The combined size of log files must be less than 4GB on 32-bit computers. The default is 5MB. Sensible values range from 1MB to 1/*N*-th of the size of the buffer pool, where *N* is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

- `innodb_log_files_in_group`

  The number of log files in the log group. `InnoDB` writes to the files in a circular fashion. The default is 2 (recommended).

- `innodb_log_group_home_dir`

  The directory path to the `InnoDB` log files. It must have the same value as `innodb_log_arch_dir`. If you do not specify any `InnoDB` log parameters, the default is to create two 5MB files names `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

- `innodb_max_dirty_pages_pct`

  This is an integer in the range from 0 to 100. The default is 90. The main thread in `InnoDB` tries to write pages from the buffer pool so that the percentage of dirty (not yet written) pages will not exceed this value. If you have the `SUPER` privilege, this percentage can be changed while the server is running:

  ```
  SET GLOBAL innodb_max_dirty_pages_pct = value;
  ```

- `innodb_max_purge_lag`

  This option controls how to delay `INSERT`, `UPDATE` and `DELETE` operations when the purge operations (see Section 15.2.12, “Implementation of Multi-Versioning”) are lagging. The default value of this parameter is zero, meaning that there are no delays. This option can be changed at runtime as a global system variable.

  The `InnoDB` transaction system maintains a list of transactions that have delete-marked index records by `UPDATE` or `DELETE` operations. Let the length of this list be *purge_lag*. When *purge_lag* exceeds `innodb_max_purge_lag`, each `INSERT`, `UPDATE` and `DELETE` operation is delayed by ((*purge_lag*/`innodb_max_purge_lag`)*10)-5 milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

  A typical setting for a problematic workload might be 1 million, assuming that our transactions are small, only 100 bytes in size, and we can allow 100 MB of unpurged rows in our tables.

- `innodb_mirrored_log_groups`

  The number of identical copies of log groups we keep for the database. Currently this should be set to 1.

- `innodb_open_files`

  This option is relevant only if you use multiple tablespaces in `InnoDB`. It specifies the maximum number of `.ibd` files that `InnoDB` can keep open at one time. The minimum value is 10. The default is 300.

The file descriptors used for `.ibd` files are for `InnoDB` only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache.

- `innodb_status_file`

  This option causes `InnoDB` to create a file `<datadir>/innodb_status.<pid>` for periodical `SHOW ENGINE INNODB STATUS` output.

- `innodb_support_xa`

  When set to `ON` or 1 (the default), this variable enables `InnoDB` support for two-phase commit in XA transactions. Enabling `innodb_support_xa` causes an extra disk flush for transaction preparation. If you don't care about using XA, you can disable this variable by setting it to `OFF` or 0 to reduce the number of disk flushes and get better `InnoDB` performance.

- `innodb_sync_spin_loops`

  The number of times a thread waits for an `InnoDB` mutex to be freed before the thread is suspended.

- `innodb_table_locks`

  `InnoDB` honors `LOCK TABLES`; MySQL does not return from `LOCK TABLE .. WRITE` until all other threads have released all their locks to the table. The default value is 1, which means that `LOCK TABLES` causes `InnoDB` to lock a table internally. In applications using `AUTOCOMMIT=1`, `InnoDB`'s internal table locks can cause deadlocks. You can set `innodb_table_locks=0` in `my.cnf` (or `my.ini` on Windows) to remove that problem.

- `innodb_thread_concurrency`

  `InnoDB` tries to keep the number of operating system threads concurrently inside `InnoDB` less than or equal to the limit given by this parameter. If you have performance issues, and `SHOW ENGINE INNODB STATUS` reveals many threads waiting for semaphores, you may have thread "thrashing" and should try setting this parameter lower or higher. If you have a computer with many processors and disks, you can try setting the value higher to make better use of your computer's resources. A recommended value is the sum of the number of processors and disks your system has. A value of 500 or greater disables concurrency checking. The default value is 20, and concurrency checking will be disabled if the setting is greater than or equal to 20.

15.2.5. Creating the `InnoDB` Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary `InnoDB` configuration parameters. Before starting MySQL, you should verify that the directories you have specified for `InnoDB` data files and log files exist and that the MySQL server has access rights to those directories. `InnoDB` cannot create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server `mysqld` from the command prompt when you create an `InnoDB` database, not from the `mysqld_safe` wrapper or as a Windows service. When you run from a command prompt you see what `mysqld` prints and what is happening. On Unix, just invoke `mysqld`. On Windows, use the `--console` option.

When you start the MySQL server after initially configuring `InnoDB` in your option file, `InnoDB` creates your data files and log files. `InnoDB` prints something like the following:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1
did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
```

```
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size
to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size
to 5242880
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
InnoDB: Started
mysqld: ready for connections
```

A new `InnoDB` database has been created. You can connect to the MySQL server with the usual MySQL client programs like `mysql`. When you shut down the MySQL server with `mysqladmin shutdown`, the output is like the following:

```
010321 18:33:34  mysqld: Normal shutdown
010321 18:33:34  mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created. The log directory also contains a small file named `ib_arch_log_0000000000`. That file resulted from the database creation, after which `InnoDB` switched off log archiving. When MySQL is started again, the data files and log files have been created, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

You can add the option `innodb_file_per_table` to `my.cnf`, and make `InnoDB` to store each table into its own `.ibd` file in a database directory of MySQL. See Section 15.2.3.1, “Using Per-Table Tablespaces”.

15.2.5.1. Dealing with `InnoDB` Initialization Problems

If `InnoDB` prints an operating system error in a file operation, usually the problem is one of the following:

- You did not create the `InnoDB` data file directory or the `InnoDB` log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot not read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options you specified.
- The disk is full or a disk quota is exceeded.
- You have created a subdirectory whose name is equal to a data file you specified.
- There is a syntax error in `innodb_data_home_dir` or `innodb_data_file_path`.

If something goes wrong when `InnoDB` attempts to initialize its tablespace or its log files, you should delete all files created by `InnoDB`. This means all `ibdata` files and all `ib_logfile`s. In case you created some `InnoDB` tables, delete the corresponding `.frm` files for these tables (and

any .ibd files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the InnoDB database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

15.2.6. Creating InnoDB Tables

Suppose that you have started the MySQL client with the command mysql test. To create an InnoDB table, you must specify an ENGINE = InnoDB or TYPE = InnoDB option in the table creation SQL statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) TYPE=InnoDB;
```

The SQL statement creates a table and an index on column a in the InnoDB tablespace that consists of the data files that you specified in my.cnf. In addition, MySQL creates a file customers.frm in the test directory under the MySQL database directory. Internally, InnoDB adds to its own data dictionary an entry for table 'test/customers'. This means you can create a table of the same name customers in some other database, and the table names do not collide inside InnoDB.

You can query the amount of free space in the InnoDB tablespace by issuing a SHOW TABLE STATUS statement for any InnoDB table. The amount of free space in the tablespace appears in the Comment section in the output of SHOW TABLE STATUS. For example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

Note that the statistics SHOW gives about InnoDB tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

15.2.6.1. How to Use Transactions in InnoDB with Different APIs

By default, each client that connects to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. To use multiple-statement transactions, you can switch autocommit off with the SQL statement SET AUTOCOMMIT = 0 and use COMMIT and ROLLBACK to commit or roll back your transaction. If you want to leave autocommit on, you can enclose your transactions within START TRANSACTION and either COMMIT or ROLLBACK. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE CUSTOMER (A INT, B CHAR (20), INDEX (A))
    -> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET AUTOCOMMIT=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM CUSTOMER;
+------+--------+
| A    | B      |
+------+--------+
|   10 | Heikki |
+------+--------+
1 row in set (0.00 sec)
mysql>
```

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

15.2.6.2. Converting `MyISAM` Tables to `InnoDB`

Important: Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the `InnoDB` type. This is an unsupported operation. The system tables must always be of the `MyISAM` type.

If you want all your (non-system) tables to be created as `InnoDB` tables, you can simply add the line `default-storage-engine=innodb` to the `[mysqld]` section of your server option file.

`InnoDB` does not have a special optimization for separate index creation the way the `MyISAM` storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to `InnoDB` is to do the inserts directly to an `InnoDB` table. That is, use `ALTER TABLE ... ENGINE=INNODB`, or create an empty `InnoDB` table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import session:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because `InnoDB` can then use its insert buffer to write secondary index records as a batch.

To get better control over the insertion process, it might be good to insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
   WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, you should increase the size of the `InnoDB` buffer pool to reduce disk I/O. Do not use more than 80% of the physical memory, though. You can also increase the sizes of the `InnoDB` log files and the log files.

Make sure that you do not fill up the tablespace: `InnoDB` tables require a lot more disk space than `MyISAM` tables. If an `ALTER TABLE` runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, `InnoDB` uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. In rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 15.2.8.1, “Forcing `InnoDB` Recovery”.

15.2.6.3. How `AUTO_INCREMENT` Columns Work in `InnoDB`

If you specify an `AUTO_INCREMENT` column for a table, the `InnoDB` table handle in the data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. The auto-increment counter is stored only in main memory, not on disk.

`InnoDB` uses the following algorithm to initialize the auto-increment counter for a table `T` that contains an `AUTO_INCREMENT` column named `ai_col`: After a server startup, when a user first does an insert to a table `T`, `InnoDB` executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM T FOR UPDATE;
```

The value retrieved by the statement is incremented by one and assigned to the column and the auto-increment counter of the table. If the table is empty, the value `1` is assigned. If the auto-increment counter is not initialized and the user invokes a `SHOW TABLE STATUS` statement that displays output for the table `T`, the counter is initialized (but not incremented) and stored for use by later inserts. Note that in this initialization we do a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

`InnoDB` follows the same procedure for initializing the auto-increment counter for a freshly created table.

Note that if the user specifies `NULL` or `0` for the `AUTO_INCREMENT` column in an `INSERT`, `InnoDB` treats the row as if the value had not been specified and generates a new value for it.

After the auto-increment counter has been initialized, if a user inserts a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value. If the user does not explicitly specify a value, `InnoDB` increments the counter by one and assigns the new value to the column.

When accessing the auto-increment counter, `InnoDB` uses a special table level `AUTO-INC` lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an `AUTO_INCREMENT` column. Two transactions cannot have the `AUTO-INC` lock on the same table simultaneously.

Note that you may see gaps in the sequence of values assigned to the `AUTO_INCREMENT` column if you roll back transactions that have gotten numbers from the counter.

The behavior of the auto-increment mechanism is not defined if a user assigns a negative value to the column or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

`InnoDB` supports the `AUTO_INCREMENT = n` table option in `CREATE TABLE` and `ALTER TABLE` statements, to set the initial counter value or alter the current counter value. The effect of this option is canceled by a server restart, for reasons discussed earlier in this section.

15.2.6.4. `FOREIGN KEY` Constraints

`InnoDB` also supports foreign key constraints. The syntax for a foreign key constraint definition in `InnoDB` looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
    REFERENCES tbl_name (index_col_name, ...)
    [ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
    [ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Foreign keys definitions are subject to the following conditions:

- Both tables must be `InnoDB` type and they must not be temporary tables.
- In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist.
- In the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that `BLOB` and `TEXT` columns cannot be included in a foreign key, because indexes on those columns must always include a prefix length.

- If the CONSTRAINT*symbol* is given, it must be unique in the database. If it is not given, InnoDB creates the name automatically.

InnoDB rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table without a matching candidate key value in the parent table. The action InnoDB takes for any UPDATE or DELETE operation that attempts to update or delete a candidate key value in the parent table that has some matching rows in the child table is dependent on the *referential action* specified using ON UPDATE and ON DETETE subclauses of the FOREIGN KEY clause. When the user attempts to delete or update a row from a parent table, and there are one or more matching rows in the child table, InnoDB supports five options regarding the action to be taken:

- CASCADE: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both ON DELETE CASCADE and ON UPDATE CASCADE are available. Between two tables, you should not define several ON UPDATE CASCADE clauses that act on the same column in the parent table or in the child table.

- SET NULL: Delete or update the row from the parent table and set the foreign key column or columns in the child table to NULL. This is only valid if the foreign key columns do not have the NOT NULL qualifier specified. Both ON DELETE SET NULL and ON UPDATE SET NULL clauses are supported.

- NO ACTION: In standard SQL, NO ACTION means *no action* in the sense that an attempt to delete or update a primary key value is not allowed to proceed if there is a related foreign key value in the referenced table. InnoDB rejects the delete or update operation for the parent table.

- RESTRICT: Rejects the delete or update operation for the parent table. NO ACTION and RESTRICT are the same as omitting the ON DELETE or ON UPDATE clause. (Some database systems have deferred checks, and NO ACTION is a deferred check. In MySQL, foreign key constraints are checked immediately, so NO ACTION and RESTRICT are the same.)

- SET DEFAULT: This action is recognized by the parser, but InnoDB rejects table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

InnoDB supports the same options when the candidate key in the parent table is updated. With CASCADE, the foreign key column or columns in the child table are set to the new values of the candidate key in the parent table. In the same way, the updates cascade if updated columns in the child table reference foreign keys in another table.

Note that InnoDB supports foreign key references within a table and in these cases child table really means dependent records within the table.

InnoDB needs indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. The index on the foreign key is created automatically. This is in contrast to some older versions, in which indexes had to be created explicitly or the creation of foreign key constraints would fail.

Corresponding columns in the foreign key and the referenced key must have similar internal data types inside InnoDB so that they can be compared without a type conversion. *The size and sign of integer types must be the same.* The length of string types need not be the same. If you specify a SET NULL action, *make sure that you have not declared the columns in the child table as NOT NULL*.

If MySQL reports an error number 1005 from a CREATE TABLE statement, and the error message refers to errno 150, this means that the table creation failed because a foreign key constraint was not correctly formed. Similarly, if an ALTER TABLE fails and it refers to errno 150, that means a foreign key definition would be incorrectly formed for the altered table. You can use SHOW ENGINE INNODB STATUS to display a detailed explanation of the most recent InnoDB foreign key error in the server.

Note: InnoDB does not check foreign key constraints on those foreign key or referenced key values

that contain a NULL column.

Deviation from SQL standards: If in the parent table there are several rows that have the same referenced key value, then InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a RESTRICT type constraint, and there is a child row with several parent rows, InnoDB does not allow the deletion of any of those parent rows.

InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

Deviation from SQL standards: A FOREIGN KEY constraint that references a non-UNIQUE key is not standard SQL. It is an InnoDB extension to standard SQL.

Deviation from SQL standards: If ON UPDATE CASCADE or ON UPDATE SET NULL recurses to update the *same table* it has previously updated during the cascade, it acts like RESTRICT. This means that you cannot use self-referential ON UPDATE CASCADE or ON UPDATE SET NULL operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential ON DELETE SET NULL, on the other hand, is possible, as is a self-referential ON DELETE CASCADE. Cascading operations may not be nested more than 15 levels deep.

Deviation from SQL standards: Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks UNIQUE and FOREIGN KEY constraints row-by-row. According to the SQL standard, the default behavior should be deferred checking, that is, constraints are only checked after the *entire SQL statement* has been processed. Until InnoDB implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself via a foreign key.

Note: Currently, triggers are not activated by cascaded foreign key actions.

A simple example that relates parent and child tables through a single-column foreign key:

```
CREATE TABLE parent(id INT NOT NULL,
                    PRIMARY KEY (id)
) ENGINE=INNODB;
CREATE TABLE child(id INT, parent_id INT,
                   INDEX par_ind (parent_id),
                   FOREIGN KEY (parent_id) REFERENCES parent(id)
                     ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a product_order table has foreign keys for two other tables. One foreign key references a two-column index in the product table. The other references a single-column index in the customer table:

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                      PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                      product_category INT NOT NULL,
                      product_id INT NOT NULL,
                      customer_id INT NOT NULL,
                      PRIMARY KEY(no),
                      INDEX (product_category, product_id),
                      FOREIGN KEY (product_category, product_id)
                        REFERENCES product(category, id)
                        ON UPDATE CASCADE ON DELETE RESTRICT,
                      INDEX (customer_id),
                      FOREIGN KEY (customer_id)
                        REFERENCES customer(id)) ENGINE=INNODB;
```

InnoDB allows you to add a new foreign key constraint to a table by using ALTER TABLE:

```
ALTER TABLE yourtablename
    ADD [CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
    REFERENCES tbl_name (index_col_name, ...)
    [ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
    [ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Remember to create the required indexes first. You can also add a self-referential foreign key constraint to a table using `ALTER TABLE`.

`InnoDB` also supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE yourtablename DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the `fk_symbol` value is internally generated by `InnoDB` when the foreign key is created. To find out the symbol when you want to drop a foreign key, use the `SHOW CREATE TABLE` statement. For example:

```
mysql> SHOW CREATE TABLE ibtest11c\G
*************************** 1. row ***************************
       Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY  (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY 0_38775;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.

The `InnoDB` parser allows you to use backticks around table and column names in a `FOREIGN KEY ... REFERENCES ...` clause. The `InnoDB` parser also takes into account the setting of the `lower_case_table_names` system variable.

`InnoDB` returns a table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

From this version, `mysqldump` also produces correct definitions of tables to the dump file, and does not forget about the foreign keys.

You can display the foreign key constraints for a table like this:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

The foreign key constraints are listed in the `Comment` column of the output.

When performing foreign key checks, `InnoDB` sets shared row-level locks on child or parent re-

cords it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit.

To make it easier to reload dump files for tables that have foreign key relationships, mysqldump automatically includes a statement in the dump output to set FOREIGN_KEY_CHECKS to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET FOREIGN_KEY_CHECKS = 0;
mysql> SOURCE dump_file_name;
mysql> SET FOREIGN_KEY_CHECKS = 1;
```

This allows you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting FOREIGN_KEY_CHECKS to 0 can also be useful for ignoring foreign key constraints during LOAD DATA and ALTER TABLE operations.

InnoDB does not allow you to drop a table that is referenced by a FOREIGN KEY constraint, unless you do SET FOREIGN_KEY_CHECKS=0. When you drop a table, the constraints that were defined in its create statement are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the right column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns error number 1005 and refers to errno 150 in the error message.

15.2.6.5. InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, you have to make a copy of the InnoDB tablespace and the log files, as well as the .frm files of the InnoDB tables, and move the copies to the slave. For the proper procedure to do this, see Section 15.2.9, “Moving an InnoDB Database to Another Machine”.

If you can shut down the master or an existing slave, you can take a cold backup of the InnoDB tablespace and log files and use that to set up a slave. To make a new slave without taking down any server you can also use the non-free (commercial) InnoDB Hot Backup tool [http://www.innodb.com/order.html].

One minor limitation in InnoDB replication is that LOAD TABLE FROM MASTER does not work for InnoDB type tables. There are two possible workarounds:

- Dump the table on the master and import the dump file into the slave.
- Use ALTER TABLE *tbl_name* ENGINE=MyISAM on the master before setting up replication with LOAD TABLE *tbl_name* FROM MASTER, and then use ALTER TABLE to convert the master table back to InnoDB afterward.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A slave reads the binary log of the master and executes the same SQL statements. However, statements that occur within a transaction are not written to the binary log until the transaction commits, at which point all statements in the transaction are written at once. If a statement fails, for example, because of a foreign key violation, or if a transaction is rolled back, no SQL statements are written to the binary log, and the transaction is not executed on the slave at all.

15.2.7. Adding and Removing InnoDB Data and Log Files

This section describes what you can do when your InnoDB tablespace runs out of room or when you want to change the size of the log files.

The easiest way to increase the size of the InnoDB tablespace is to configure it from the beginning to be auto-extending. Specify the autoextend attribute for the last data file in the tablespace definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be configured setting the value of innodb_autoextend_increment, which is measured in megabytes,and whose default value is 8.

Alternatively, you can increase the size of your tablespace by adding another data file. To do this, you have to shut down the MySQL server, edit the my.cnf file to add a new data file to the end of innodb_data_file_path, and start the server again.

If your last data file was defined with the keyword autoextend, the procedure to edit my.cnf must take into account the size to which the last data file has grown. Obtain the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify the rounded size explicitly in innodb_data_file_path. Then you can add another data file. Remember that only the last data file in the innodb_data_file_path can be specified as auto-extending.

As an example, assume that the tablespace has just one auto-extending data file ibdata1:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after adding another auto-extending data file.

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new file to the tablespace, make sure that it does not exist. InnoDB creates and initializes the file when you restart the server.

Currently, you cannot remove a data file from the tablespace. To decrease the size of your tablespace, use this procedure:

1. Use mysqldump to dump all your InnoDB tables.
2. Stop the server.
3. Remove all the existing tablespace files.
4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

If you want to change the number or the size of your InnoDB log files, you have to stop the MySQL server and make sure that it shuts down without errors. Then copy the old log files into a safe place just in case something went wrong in the shutdown and you need them to recover the tablespace. Delete the old log files from the log file directory, edit my.cnf to change the log file configuration, and start the MySQL server again. mysqld sees that no log files exist at startup and tells you that it is creating new ones.

15.2.8. Backing Up and Recovering an InnoDB Database

The key to safe database management is taking regular backups.

`InnoDB Hot Backup` is an online backup tool you can use to backup your `InnoDB` database while it is running. `InnoDB Hot Backup` does not require you to shut down your database and it does not set any locks or disturb your normal database processing. `InnoDB Hot Backup` is a non-free (commercial) add-on tool whose annual license fee is €390 per computer on which the MySQL server is run. See the `InnoDB Hot Backup` home page [http://www.innodb.com/order.html] for detailed information and screenshots.

If you are able to shut down your MySQL server, you can make a binary backup that consists of all files used by `InnoDB` to manage its tables. Use the following procedure:

1. Shut down your MySQL server and make sure that it shuts down without errors.
2. Copy all your data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all your `ib_logfile` files to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.
5. Copy all the `.frm` files for your `InnoDB` tables to a safe place.

Replication works with `InnoDB` tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

In addition to taking binary backups as just described, you should also regularly take dumps of your tables with `mysqldump`. The reason for this is that a binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, since the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option that you can use to take a consistent snapshot without locking out other clients.

To be able to recover your `InnoDB` database to the present from the binary backup just described, you have to run your MySQL server with binary logging turned on. Then you can apply the binary log to the backup database to achieve point-in-time recovery:

```
mysqlbinlog yourhostname-bin.123 | mysql
```

To recover from a crash of your MySQL server, the only requirement is to restart it. `InnoDB` automatically checks the logs and performs a roll-forward of the database to the present. `InnoDB` automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
```

```
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database gets corrupted or your disk fails, you have to do the recovery from a backup. In the case of corruption, you should first find a backup that is not corrupted. After restoring the base backup, do the recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes performed after the backup was made.

In some cases of database corruption it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use `innodb_tablespace_monitor` to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption.

15.2.8.1. Forcing InnoDB Recovery

If there is database page corruption, you may want to dump your tables from the database with `SELECT INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Even so, the corruption may cause `SELECT * FROM` *`tbl_name`* statements or `InnoDB` background operations to crash or assert, or even make `InnoDB` roll-forward recovery crash. However, you can force the `InnoDB` storage engine to start up while preventing background operations from running, so that you are able to dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 4
```

The allowable non-zero values for `innodb_force_recovery` follow. A larger number includes all precautions of smaller numbers. If you are able to dump your tables with an option value of at most 4, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is more drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

- `1` (`SRV_FORCE_IGNORE_CORRUPT`)

  Let the server run even if it detects a corrupt page. Try to make `SELECT * FROM` *`tbl_name`* jump over corrupt index records and pages, which helps in dumping tables.

- `2` (`SRV_FORCE_NO_BACKGROUND`)

  Prevent the main thread from running. If a crash would occur during the purge operation, this recovery value prevents it.

- `3` (`SRV_FORCE_NO_TRX_UNDO`)

  Do not run transaction rollbacks after recovery.

- `4` (`SRV_FORCE_NO_IBUF_MERGE`)

  Prevent also insert buffer merge operations. If they would cause a crash, do not do them. Do not calculate table statistics.

- `5` (`SRV_FORCE_NO_UNDO_LOG_SCAN`)

Do not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed.

- 6 (SRV_FORCE_NO_LOG_REDO)

  Do not do the log roll-forward in connection with recovery.

You can SELECT from tables to dump them, or DROP or CREATE tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or ALTER TABLE. You can kill the mysqld process and set innodb_force_recovery to 3 to bring the database up without the rollback, then DROP the table that is causing the runaway rollback.

The database must not otherwise be used with any non-zero value of innodb_force_recovery. As a safety measure, InnoDB prevents users from performing INSERT, UPDATE, or DELETE operations when innodb_force_recovery is greater than 0.

15.2.8.2. Checkpoints

InnoDB implements a checkpoint mechanism known as "fuzzy" checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

InnoDB writes to its log files on a rotating basis. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case InnoDB has to do a recovery. This means that when InnoDB starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that InnoDB is going to reuse. In other words, InnoDB must create a checkpoint and this often involves flushing of modified database pages to disk.

The preceding description explains why making your log files very large may save disk I/O in checkpointing. It often makes sense to set the total size of the log files as big as the buffer pool or even bigger. The drawback of using large log files is that crash recovery can take longer because there is more logged information to apply to the database.

15.2.9. Moving an InnoDB Database to Another Machine

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, you should have all table and database names in lowercase. A convenient way to accomplish this is to add the following line to the [mysqld] section of your my.cnf or my.ini file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. You can move an InnoDB database simply by copying all the relevant files listed in Section 15.2.8, "Backing Up and Recovering an InnoDB Database". If the floating-point formats differ but you have not used FLOAT or DOUBLE data types in your tables, then the procedure is the same: simply copy the relevant files. If the formats differ and your tables contain floating-point data, you must use mysqldump to dump your tables on one machine and

then import the dump files on the other machine.

One way to increase performance is to switch off autocommit mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

15.2.10. InnoDB Transaction Model and Locking

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as non-locking consistent reads by default, in the style of Oracle. The lock table in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically several users are allowed to lock every row in the database, or any random subset of the rows, without InnoDB running out of memory.

15.2.10.1. InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks:

- A shared (*S*) lock allows a transaction to read a row (tuple).
- An exclusive (*X*) lock allows a transaction to update or delete a row.

If transaction T1 holds a shared (*S*) lock on tuple t, then

- A request from some distinct transaction T2 for an *S* lock on t can be granted immediately. As a result, both T1 and T2 hold an *S* lock on t.
- A request from some distinct transaction T2 for an *X* lock on t cannot be granted immediately.

If a transaction T1 holds an exclusive (*X*) lock on tuple t, then a request from some distinct transaction T2 for a lock of either type on t cannot be granted immediately. Instead, transaction T2 has to wait for transaction T1 to release its lock on tuple t.

Additionally, InnoDB supports *multiple granularity locking* which allows coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in InnoDB. The idea behind intention locks is for a transaction to indicate which type of lock (shared or exclusive) it will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction T has requested a lock of the indicated type on table R):

- Intention shared (*IS*): Transaction T intends to set *S* locks on individual rows in table R.
- Intention exclusive (*IX*): Transaction T intends to set *X* locks on those rows.

The intention locking protocol is as follows:

- Before a given transaction can acquire an *S* lock on a given row, it must first acquire an *IS* or stronger lock on the table containing that row.
- Before a given transaction can acquire an *X* lock on a given row, it must first acquire an *IX* lock on the table containing that row.

These rules can be conveniently summarized by means of a *lock type compatibility matrix*:

	X	*IX*	*S*	*IS*

X	Conflict	Conflict	Conflict	Conflict
IX	Conflict	Compatible	Conflict	Compatible
S	Conflict	Conflict	Compatible	Compatible
IS	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks. A lock is not granted to a requesting transaction if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of *IX* and *IS* locks is to show that someone is locking a row, or going to lock a row in the table.

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an *S* lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+------+
| i    |
+------+
|    1 |
+------+
1 row in set (0.10 sec)
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B is already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, `InnoDB` generates an error for client A and releases its locks. At that point, the lock request for client B can be granted and B deletes the row from the table.

15.2.10.2. InnoDB and AUTOCOMMIT

In InnoDB, all user activity occurs inside a transaction. If the autocommit mode is enabled, each SQL statement forms a single transaction on its own. MySQL always starts a new connection with autocommit enabled.

If the autocommit mode is switched off with SET AUTOCOMMIT = 0, then we can consider that a user always has a transaction open. A SQL COMMIT or ROLLBACK statement ends the current transaction and a new one starts. Both statements release all InnoDB locks that were set during the current transaction. A COMMIT means that the changes made in the current transaction are made permanent and become visible to other users. A ROLLBACK statement, on the other hand, cancels all modifications made by the current transaction.

If the connection has autocommit enabled, the user can still perform a multiple-statement transaction by starting it with an explicit START TRANSACTION or BEGIN statement and ending it with COMMIT or ROLLBACK.

15.2.10.3. InnoDB and TRANSACTION ISOLATION LEVEL

In terms of the SQL:1992 transaction isolation levels, the InnoDB default is REPEATABLE READ. InnoDB offers all four transaction isolation levels described by the SQL standard. You can set the default isolation level for all connections by using the --transaction-isolation option on the command line or in option files. For example, you can set the option in the [mysqld] section of my.cnf like this:

```
[mysqld]
transaction-isolation = {READ-UNCOMMITTED | READ-COMMITTED
                         | REPEATABLE-READ | SERIALIZABLE}
```

A user can change the isolation level of a single session or all new incoming connections with the SET TRANSACTION statement. Its syntax is as follows:

```
SET [SESSION | GLOBAL] TRANSACTION ISOLATION LEVEL
                       {READ UNCOMMITTED | READ COMMITTED
                        | REPEATABLE READ | SERIALIZABLE}
```

Note that there are hyphens in the level names for the --transaction-isolation option, but not for the SET TRANSACTION statement.

The default behavior is to set the isolation level for the next (not started) transaction. If you use the GLOBAL keyword, the statement sets the default transaction level globally for all new connections created from that point on (but not existing connections). You need the SUPER privilege to do this. Using the SESSION keyword sets the default transaction level for all future transactions performed on the current connection.

Any client is free to change the session isolation level (even in the middle of a transaction), or the isolation level for the next transaction.

You can query the global and session transaction isolation levels with these statements:

```
SELECT @@global.tx_isolation;
SELECT @@tx_isolation;
```

In row-level locking, InnoDB uses next-key locking. That means that besides index records, InnoDB can also lock the “gap” preceding an index record to block insertions by other users immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that only locks a gap before some index record.

A detailed description of each isolation level in InnoDB follows:

- `READ UNCOMMITTED`

  `SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a record might be used. Thus, using this isolation level, such reads are not consistent. This is also called a “dirty read”. Otherwise, this isolation level works like `READ COMMITTED`.

- `READ COMMITTED`

  A somewhat Oracle-like isolation level. All `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` statements lock only the index records, not the gaps before them, and thus allow the free insertion of new records next to locked records. `UPDATE` and `DELETE` statements using a unique index with a unique search condition lock only the index record found, not the gap before it. In range-type `UPDATE` and `DELETE` statements, `InnoDB` must set next-key or gap locks and block insertions by other users to the gaps covered by the range. This is necessary because “phantom rows” must be blocked for MySQL replication and recovery to work.

  Consistent reads behave as in Oracle: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See Section 15.2.10.4, “Consistent Non-Locking Read”.

- `REPEATABLE READ`

  This is the default isolation level of `InnoDB`. `SELECT ... FOR UPDATE`, `SELECT ... LOCK IN SHARE MODE`, `UPDATE`, and `DELETE` statements that use a unique index with a unique search condition lock only the index record found, not the gap before it. With other search conditions, these operations employ next-key locking, locking the index range scanned with next-key or gap locks, and block new insertions by other users.

  In consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the same snapshot established by the first read. This convention means that if you issue several plain `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See Section 15.2.10.4, “Consistent Non-Locking Read”.

- `SERIALIZABLE`

  This level is like `REPEATABLE READ`, but `InnoDB` implicitly commits all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE`.

15.2.10.4. Consistent Non-Locking Read

A consistent read means that `InnoDB` uses multi-versioning to present to a query a snapshot of the database at a point in time. The query see the changes made by those transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction.

If you are running with the default `REPEATABLE READ` isolation level, all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

Consistent read is the default mode in which `InnoDB` processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other users are free to modify those tables at the same time a consistent read is being performed on the table.

Note that consistent read does not work over `DROP TABLE` and over `ALTER TABLE`. Consistent read does not work over `DROP TABLE` because MySQL can't use a table that has been dropped and `InnoDB` destroys the table. Consistent read does not work over `ALTER TABLE` because it is executed inside of the transaction that creates a new table and inserts rows from the old table to the new table. When you reissue the consistent read, it will not see any rows in the new table, because they were inserted in a transaction that is not visible in the snapshot read by the consistent read.

15.2.10.5. SELECT … FOR UPDATE and SELECT … LOCK IN SHARE MODE Locking Reads

In some circumstances, a consistent read is not convenient. For example, you might want to add a new row into your table `child`, and make sure that the child has a parent in table `parent`. The following example shows how to implement referential integrity in your application code.

Suppose that you use a consistent read to read the table `parent` and indeed see the parent of the child in the table. Can you safely add the child row to table `child`? No, because it may happen that meanwhile some other user deletes the parent row from the table `parent` without you being aware of it.

The solution is to perform the `SELECT` in a locking mode using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

Performing a read in share mode means that we read the latest available data, and set a shared mode lock on the rows we read. A shared mode lock prevents others from updating or deleting the row we have read. Also, if the latest data belongs to a yet uncommitted transaction of another client connection, we wait until that transaction commits. After we see that the preceding query returns the parent `'Jones'`, we can safely add the child record to the `child` table and commit our transaction.

Let us look at another example: We have an integer counter field in a table `child_codes` that we use to assign a unique identifier to each child added to table `child`. Obviously, using a consistent read or a shared mode read to read the present value of the counter is not a good idea, since two users of the database may then see the same value for the counter, and a duplicate-key error occurs if two users attempt to add children with the same identifier to the table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when attempting to update the counter.

In this case, there are two good ways to implement the reading and incrementing of the counter: (1) update the counter first by incrementing it by 1 and only after that read it, or (2) read the counter first with a lock mode `FOR UPDATE`, and increment after that. The latter approach can be implemented as follows:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

Locks set by `IN SHARE MODE` and `FOR UPDATE` reads are released when the transaction is committed or rolled back.

15.2.10.6. Next-Key Locking: Avoiding the Phantom Problem

In row-level locking, `InnoDB` uses an algorithm called *next-key locking*. `InnoDB` performs the row-level locking in such a way that when it searches or scans an index of a table, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index re-

cord locks.

The locks InnoDB sets on index records also affect the "gap" before that index record. If a user has a shared or exclusive lock on record R in an index, another user cannot insert a new index record immediately before R in the index order. This locking of gaps is done to prevent the so-called "phantom problem". Suppose that you want to read and lock all children from the child table having an identifier value greater than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the id column. The query scans that index starting from the first record where id is bigger than 100. If the locks set on the index records would not lock out inserts made in the gaps, a new row might meanwhile be inserted to the table. If you execute the same SELECT within the same transaction, you would see a new row in the result set returned by the query. This is contrary to the isolation principle of transactions: A transaction should be able to run so that the data it has read does not change during the transaction. If we regard a set of rows as a data item, the new "phantom" child would violate this isolation principle.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the previous example: The locks set by InnoDB prevent any insert to the table where id would be bigger than 100.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking allows you to "lock" the non-existence of something in your table.

15.2.10.7. An Example of Consistent Read in InnoDB

Suppose that you are running in the default REPEATABLE READ isolation level. When you issue a consistent read, that is, an ordinary SELECT statement, InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

You can advance your timepoint by committing your transaction and then doing another SELECT.

This is called *multi-versioned concurrency control*.

```
                User A                  User B

            SET AUTOCOMMIT=0;       SET AUTOCOMMIT=0;
time
|           SELECT * FROM t;
|           empty set
|                                   INSERT INTO t VALUES (1, 2);
|
v           SELECT * FROM t;
            empty set
                                    COMMIT;

            SELECT * FROM t;
            empty set

            COMMIT;

            SELECT * FROM t;
            ---------------------
            |    1    |    2    |
            ---------------------
            1 row in set
```

In this example, user A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

If you want to see the "freshest" state of the database, you should use either the READ COMMITTED isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

15.2.10.8. Locks Set by Different SQL Statements in InnoDB

A locking read, an UPDATE, or a DELETE generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter if there are WHERE conditions in the statement that would exclude the row. InnoDB does not remember the exact WHERE condition, but only knows which index ranges were scanned. The record locks are normally next-key locks that also block inserts to the "gap" immediately before the record.

If the locks to be set are exclusive, InnoDB always retrieves also the clustered index record and sets a lock on it.

If you do not have indexes suitable for your statement and MySQL has to scan the whole table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily need to scan many rows.

InnoDB sets specific types of locks as follows:

- SELECT ... FROM is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to SERIALIZABLE. For SERIALIZABLE level, this sets shared next-key locks on the index records it encounters.
- SELECT ... FROM ... LOCK IN SHARE MODE sets shared next-key locks on all index records the read encounters.
- SELECT ... FROM ... FOR UPDATE sets exclusive next-key locks on all index records the read encounters.
- INSERT INTO ... VALUES (...) sets an exclusive lock on the inserted row. Note that this lock is not a next-key lock and does not prevent other users from inserting to the gap before the inserted row. If a duplicate-key error occurs, a shared lock on the duplicate index record is set.
- While initializing a previously specified AUTO_INCREMENT column on a table, InnoDB sets an exclusive lock on the end of the index associated with the AUTO_INCREMENT column. In accessing the auto-increment counter, InnoDB uses a specific table lock mode AUTO-INC where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. See Section 15.2.10.2, "InnoDB and AUTOCOMMIT".

  InnoDB fetches the value of a previously initialized AUTO_INCREMENT column without setting any locks.
- INSERT INTO T SELECT ... FROM S WHERE ... sets an exclusive (non-next-key) lock on each row inserted into T. It does the search on S as a consistent read, but sets shared next-key locks on S if MySQL binary logging is turned on. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement has to be executed in exactly the same way it was done originally.
- CREATE TABLE ... SELECT ... performs the SELECT as a consistent read or with shared locks, as in the previous item.
- REPLACE is done like an insert if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row that has to be updated.

- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. `InnoDB` also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the `InnoDB` layer that sets these locks. `InnoDB` is aware of table locks if `innodb_table_locks=1` (the default) and `AUTOCOMMIT=0`, and the MySQL layer above `InnoDB` knows about row-level locks. Otherwise, `InnoDB`'s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, since the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another user currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 15.2.10.10, "Deadlock Detection and Rollback". See also Section 15.2.16, "Restrictions on `InnoDB` Tables".

15.2.10.9. Implicit Transaction Commit and Rollback

By default, MySQL begins each client connection with autocommit mode enabled. When autocommit is enabled, MySQL does a commit after each SQL statement if that statement did not return an error. If an SQL statement returns an error, the commit or rollback behavior depends on the error. See Section 15.2.15, "`InnoDB` Error Handling".

If you have the autocommit mode off and close a connection without explicitly committing the final transaction, MySQL rolls back that transaction.

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a `COMMIT` before executing the statement:

- `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER TABLE`, `BEGIN`, `CREATE DATABASE`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `DROP DATABASE`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `LOAD MASTER DATA`, `LOCK TABLES`, `RENAME TABLE`, `SET AUTOCOMMIT=1`, `START TRANSACTION`, `TRUNCATE`, `UNLOCK TABLES`.
- `UNLOCK TABLES` commits a transaction only if any tables are currently locked.
- The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

Transactions cannot be nested. This is a consequence of the implicit `COMMIT` performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

15.2.10.10. Deadlock Detection and Rollback

`InnoDB` automatically detects a deadlock of transactions and rolls back a transaction or transactions to break the deadlock. `InnoDB` tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

`InnoDB` is aware of table locks if `innodb_table_locks=1` (the default) and `AUTOCOMMIT=0`, and the MySQL layer above it knows about row-level locks. Otherwise, `InnoDB` cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than `InnoDB` is involved. You must resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

15.2.10.11. How to Cope with Deadlocks

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use SHOW ENGINE INNODB STATUS to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Commit your transactions often. Small transactions are less prone to collision.
- If you are using locking reads (SELECT ... FOR UPDATE or ... LOCK IN SHARE MODE), try using a lower isolation level such as READ COMMITTED.
- Access your tables and rows in a fixed order. Then transactions form well-defined queues and do not deadlock.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use EXPLAIN SELECT to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to allow a SELECT to return data from an old snapshot, do not add the clause FOR UPDATE or LOCK IN SHARE MODE to it. Using the READ COMMITTED isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use LOCK TABLES with transactional tables, such as InnoDB tables, is to set AUTOCOMMIT = 0 and not to call UNLOCK TABLES until after you commit the transaction explicitly. For example, if you need to write to table t1 and read from table t2, you can do this:

  ```
  SET AUTOCOMMIT=0;
  LOCK TABLES t1 WRITE, t2 READ, ...;
  ... do something with tables t1 and t2 here ...
  COMMIT;
  UNLOCK TABLES;
  ```

  Table-level locks make your transactions queue nicely, and deadlocks are avoided.
- Another way to serialize transactions is to create an auxiliary "semaphore" table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.
- In applications that use the LOCK TABLES command, MySQL does not set InnoDB table

locks if AUTOCOMMIT=1.

15.2.11. InnoDB Performance Tuning Tips

- If the Unix top tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound. Maybe you are making too many transaction commits, or the buffer pool is too small. Making the buffer pool bigger can help, but do not set it equal to more than 80% of physical memory.

- Wrap several modifications into one transaction. InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. Since the rotation speed of a disk is typically at most 167 revolutions/second, that constrains the number of commits to the same 167^{th} of a second if the disk does not "fool" the operating system.

- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the innodb_flush_log_at_trx_commit parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.

- Make your log files big, even as big as the buffer pool. When InnoDB has written the log files full, it has to write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. The drawback of big log files is that the recovery time is longer.

- Make the log buffer quite large as well (on the order of 8MB).

- Use the VARCHAR data type instead of CHAR if you are storing variable-length strings or if the column may contain many NULL values. A CHAR(*N*) column always takes *N* characters to store data, even if the string is shorter or its value is NULL. Smaller tables fit better in the buffer pool and reduce disk I/O.

  When using row_format=compact (the default InnoDB record format in MySQL 5.1) and variable-length character sets, such as utf8 or sjis, CHAR(*N*) will occupy a variable amount of space, at least *N* bytes.

- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix fsync() call (which InnoDB uses by default) and other similar methods is surprisingly slow. If you are dissatisfied with database write performance, you might try setting the innodb_flush_method parameter to O_DSYNC. Although O_DSYNC seems to be slower on most systems, yours might not be one of them.

- When using the InnoDB storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), it is important to mount any filesystems used for storing InnoDB-related files using the forcedirectio option. (The default on Solaris 10/x86_64 is *not* to use this option.) Failure to use forcedirectio causes a serious degradation of InnoDB's speed and performance on this platform.

  When using the InnoDB storage engine with a large innodb_buffer_pool_size value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), a significant performance gain can be achieved by placing InnoDB data files and log files on raw devices or on a separate direct I/O UFS filesystem (using mount option forcedirectio; see mount_ufs(1M)). Users of the Veritas filesystem VxFS should use the mount option convosync=direct.

  Other MySQL data files, such as those for MyISAM tables, should not be placed on a direct I/O filesystem. Executables or libraries *must not* be placed on a direct I/O filesystem.

- When importing data into InnoDB, make sure that MySQL does not have autocommit mode enabled because that requires a log flush to disk for every insert. To disable autocommit during your import operation, surround it with SET AUTOCOMMIT and COMMIT statements:

  ```
  SET AUTOCOMMIT=0;
  ```

```
... SQL import statements ...
COMMIT;
```

If you use the `mysqldump` option `--opt`, you get dump files that are fast to import into an `InnoDB` table, even without wrapping them with the `SET AUTOCOMMIT` and `COMMIT` statements.

- Beware of big rollbacks of mass inserts: `InnoDB` uses the insert buffer to save disk I/O in inserts, but no such mechanism is used in a corresponding rollback. A disk-bound rollback can take 30 times as long to perform as the corresponding insert. Killing the database process does not help because the rollback starts again on server startup. The only way to get rid of a runaway rollback is to increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or to use a special procedure. See Section 15.2.8.1, “Forcing `InnoDB` Recovery”.

- Beware also of other big disk-bound operations. Use `DROP TABLE` and `CREATE TABLE` to empty a table, not `DELETE FROM tbl_name`.

- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

  ```
  INSERT INTO yourtable VALUES (1,2), (5,5), ...;
  ```

  This tip is valid for inserts into any table, not just `InnoDB` tables.

- If you have `UNIQUE` constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

  ```
  SET UNIQUE_CHECKS=0;
  ... import operation ...
  SET UNIQUE_CHECKS=1;
  ```

  For big tables, this saves a lot of disk I/O because `InnoDB` can use its insert buffer to write secondary index records in a batch.

- If you have `FOREIGN KEY` constraints in your tables, you can speed up table imports by turning the foreign key checks off for the duration of the import session:

  ```
  SET FOREIGN_KEY_CHECKS=0;
  ... import operation ...
  SET FOREIGN_KEY_CHECKS=1;
  ```

  For big tables, this can save a lot of disk I/O.

- If you often have recurring queries for tables that are not updated frequently, use the query cache:

  ```
  [mysqld]
  query_cache_type = ON
  query_cache_size = 10M
  ```

15.2.11.1. `SHOW ENGINE INNODB STATUS` and the `InnoDB` Monitors

`InnoDB` includes `InnoDB` Monitors that print information about the `InnoDB` internal state. You can use the `SHOW ENGINE INNODB STATUS` SQL statement at any time to fetch the output of the standard `InnoDB` Monitor to your SQL client. This information is useful in performance tuning. (If you are using the `mysql` interactive SQL client, the output is more readable if you replace the

usual semicolon statement terminator with \G.) For a discussion of InnoDB lock modes, see Section 15.2.10.1, "InnoDB Lock Modes".

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Another way to use InnoDB Monitors is to let them periodically write data to the standard output of the mysqld server. In this case, no output is sent to clients. When switched on, InnoDB Monitors print data about every 15 seconds. Server output usually is directed to the .err log in the MySQL data directory. This data is useful in performance tuning. On Windows, you must start the server from a command prompt in a console window with the --console option if you want to direct the output to the window rather than to the error log.

Monitor output includes the following types of information:

- Table and record locks held by each active transaction
- Lock waits of a transactions
- Semaphore waits of threads
- Pending file I/O requests
- Buffer pool statistics
- Purge and insert buffer merge activity of the main InnoDB thread

To cause the standard InnoDB Monitor to write to the standard output of mysqld, use the following SQL statement:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

The monitor can be stopped by issuing the following statement:

```
DROP TABLE innodb_monitor;
```

The CREATE TABLE syntax is just a way to pass a command to the InnoDB engine through MySQL's SQL parser: The only things that matter are the table name innodb_monitor and that it be an InnoDB table. The structure of the table is not relevant at all for the InnoDB Monitor. (This syntax may If you shut down the server, the monitor does not restart automatically when you restart the server. You must drop the monitor table and issue a new CREATE TABLE statement to start the monitor. change in a future release.)

You can use innodb_lock_monitor in a similar fashion. This is the same as innodb_monitor, except that it also provides a great deal of lock information. A separate innodb_tablespace_monitor prints a list of created file segments existing in the tablespace and validates the tablespace allocation data structures. In addition, there is innodb_table_monitor with which you can print the contents of the InnoDB internal data dictionary.

A sample of InnoDB Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************
Status:

END OF INNODB MONITOR OUTPUT
============================
```

Some notes on the output:

- If the `TRANSACTIONS` section reports lock waits, your applications may have lock contention. The output can also help to trace the reasons for transaction deadlocks.
- The `SEMAPHORES` section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside `InnoDB`. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting `innodb_thread_concurrency` smaller than the default value can help in such situations.
- The `BUFFER POOL AND MEMORY` section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.
- The `ROW OPERATIONS` section shows what the main thread is doing.

`InnoDB` sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, in order to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.`*`pid`*, where *`pid`* is the server process ID. `InnoDB` removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see if they contain useful information about the cause of abnormal shutdowns. The `innodb_status.`*`pid`* file is created only if the configuration option `innodb_status_file=1` is set.

15.2.12. Implementation of Multi-Versioning

Because `InnoDB` is a multi-versioned storage engine, it must keep information about old versions of rows in the tablespace. This information is stored in a data structure called a *rollback segment*

(after an analogous data structure in Oracle).

Internally, InnoDB adds two fields to each row stored in the database. A 6-byte field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

You must remember to commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space need for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. Only when InnoDB can discard the update undo log record written for the deletion can it also physically remove the corresponding row and its index records from the database. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

In a scenario where the user inserts and deletes rows in smallish batches at about the same rate in the table, it is possible that the purge thread starts to lag behind, and the table grows bigger and bigger, making everything disk-bound and very slow. Even if the table carries just 10 MB of useful data, it may grow to occupy 10 GB with all the “dead” rows. In such a case, it would be good to throttle new row operations, and allocate more resources to the purge thread. The innodb_max_purge_lag system variable exists for exactly this purpose. See Section 15.2.4, “InnoDB Startup Options and System Variables”, for more information.

15.2.13. InnoDB Table and Index Structures

MySQL stores its data dictionary information for tables in .frm files in database directories. This is true for all MySQL storage engines. But every InnoDB table also has its own entry in the InnoDB internal data dictionary inside the tablespace. When MySQL drops a table or a database, it has to delete both an .frm file or files, and the corresponding entries inside the InnoDB data dictionary. This is the reason why you cannot move InnoDB tables between databases simply by moving the .frm files.

Every InnoDB table has a special index called the *clustered index* where the data for the rows is stored. If you define a PRIMARY KEY on your table, the index of the primary key is the clustered index.

If you do not define a PRIMARY KEY for your table, MySQL picks the first UNIQUE index that has only NOT NULL columns as the primary key and InnoDB uses it as the clustered index. If there is no such index in the table, InnoDB internally generates a clustered index where the rows are ordered by the row ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O

when compared to the traditional solution. (In many database systems, data storage uses a different page from the index record.)

In InnoDB, the records in non-clustered indexes (also called secondary indexes) contain the primary key value for the row. InnoDB uses this primary key value to search for the row from the clustered index. Note that if the primary key is long, the secondary indexes use more space.

InnoDB compares CHAR and VARCHAR strings of different lengths such that the remaining length in the shorter string is treated as if padded with spaces.

15.2.13.1. Physical Structure of an Index

All InnoDB indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, InnoDB tries to contract the index tree to free the page.

15.2.13.2. Insert Buffering

It is a common situation in database applications that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus, the insertions to the clustered index do not require random reads from a disk.

On the other hand, secondary indexes are usually non-unique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in InnoDB.

If an index record should be inserted to a non-unique secondary index, InnoDB checks whether the secondary index page is in the buffer pool. If that is the case, InnoDB does the insertion directly to the index page. If the index page is not found in the buffer pool, InnoDB inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

Periodically, the insert buffer is merged into the secondary index trees in the database. Often it is possible to merge several insertions to the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen *after* the inserting transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see Section 15.2.8.1, “Forcing InnoDB Recovery”).

The insert buffer merging may take many hours, when many secondary indexes must be updated, and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see Section 15.2.12, “Implementation of Multi-Versioning”).

15.2.13.3. Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. InnoDB has a mechanism that monitors index searches made to the indexes defined for a table. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

Note that the hash index is always built based on an existing B-tree index on the table. InnoDB can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that InnoDB observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. InnoDB builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, InnoDB tailors itself through the adaptive hash index mechanism to ample main memory, coming closer to the architecture of main-memory databases.

15.2.13.4. Physical Record Structure

Records in InnoDB tables have the following characteristics:

- Each index record contains a six-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- A record contains also a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, InnoDB stores fixed-length character columns such as CHAR(10) in a fixed-length format. InnoDB truncates trailing spaces from VARCHAR columns.
- An SQL NULL value reserves 1 or 2 bytes in the record directory. Besides that, an SQL NULL value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. The motivation behind reserving the fixed space for NULL values is that it enables an update of the column from NULL to a non-NULL value to be done in place without causing fragmentation of the index page.

15.2.14. InnoDB File Space Management and Disk I/O

15.2.14.1. Disk I/O

InnoDB uses simulated asynchronous disk I/O: InnoDB creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

InnoDB uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for fsync() operations.

Doublewrite means that before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

15.2.14.2. File Space Management

The data files that you define in the configuration file form the tablespace of `InnoDB`. The files are simply concatenated to form the tablespace. There is no striping in use. Currently you cannot define where within the tablespace your tables are allocated. However, in a newly created tablespace, `InnoDB` allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of 64 consecutive pages. The "files" inside a tablespace are called *segments* in `InnoDB`. The term "rollback segment" is somewhat confusing because it actually contains many tablespace segments.

Two segments are allocated for each index in `InnoDB`. One is for non-leaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

When a segment grows inside the tablespace, `InnoDB` allocates the first 32 pages to it individually. After that `InnoDB` starts to allocate whole extents to the segment. `InnoDB` can add to a large segment up to 4 extents at a time to ensure good sequentiality of data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an `InnoDB` tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, `InnoDB` reports the extents that are definitely free in the tablespace. `InnoDB` always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, `InnoDB` contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads. (See Section 15.2.12, "Implementation of Multi-Versioning".)

15.2.14.3. Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

A symptom of fragmentation is that a table takes more space than it "should" take. How much that is exactly, is difficult to determine. All `InnoDB` data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it "should" take:

```
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

(In the preceding query, we are "fooling" the SQL optimizer into scanning the clustered index, rather than a secondary index.) Most disks can read 10 to 50 MB/s, which can be used to estimate how fast a table scan should run.

It can speed up index scans if you periodically perform a "null" `ALTER TABLE` operation:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

That causes MySQL to rebuild the table. Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions to an index are always ascending and records are deleted only from the end, the

InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

15.2.15. InnoDB Error Handling

Error handling in InnoDB is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause the rollback of that statement. InnoDB sometimes rolls back only part of the statement, or the whole transaction. The following items describe how InnoDB performs error handling:

- If you run out of file space in the tablespace, a MySQL `Table is full` error occurs and InnoDB rolls back the SQL statement.
- A transaction deadlock causes InnoDB to roll back the entire transaction. In the case of a lock wait timeout, InnoDB rolls back only the most recent SQL statement.

  When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was START TRANSACTION or BEGIN statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of COMMIT, ROLLBACK, or some SQL statement that causes an implicit commit.
- A duplicate-key error rolls back the SQL statement, if you have not specified the IGNORE option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit ROLLBACK SQL command, SHOW PROCESSLIST displays `Rolling back` in the State column for the relevant connection.

15.2.15.1. InnoDB Error Codes

The following is a non-exhaustive list of common InnoDB-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- `1005 (ER_CANT_CREATE_TABLE)`

  Cannot create table. If the error message refers to errno 150, table creation failed because a foreign key constraint was not correctly formed.
- `1016 (ER_CANT_OPEN_FILE)`

  Cannot find the InnoDB table from the InnoDB data files, although the .frm file for the table exists. See Section 15.2.17.1, “Troubleshooting InnoDB Data Dictionary Operations”.
- `1114 (ER_RECORD_FILE_FULL)`

  InnoDB has run out of free space in the tablespace. You should reconfigure the tablespace to add a new data file.
- `1205 (ER_LOCK_WAIT_TIMEOUT)`

  Lock wait timeout expired. Transaction was rolled back.
- `1213 (ER_LOCK_DEADLOCK)`

Transaction deadlock. You should rerun the transaction.

- `1216 (ER_NO_REFERENCED_ROW)`

  You are trying to add a row but there is no parent row, and a foreign key constraint fails. You should add the parent row first.

- `1217 (ER_ROW_IS_REFERENCED)`

  You are trying to delete a parent row that has children, and a foreign key constraint fails. You should delete the children first.

15.2.15.2. Operating System Error Codes

To print the meaning of an operating system error number, use the `perror` program that comes with the MySQL distribution.

The following table provides a list of some common Linux system error codes. For a more complete list, see Linux source code [http://www.iglu.org.il/lxr/source/include/asm-i386/errno.h].

- `1 (EPERM)`

  Operation not permitted

- `2 (ENOENT)`

  No such file or directory

- `3 (ESRCH)`

  No such process

- `4 (EINTR)`

  Interrupted system call

- `5 (EIO)`

  I/O error

- `6 (ENXIO)`

  No such device or address

- `7 (E2BIG)`

  Arg list too long

- `8 (ENOEXEC)`

  Exec format error

- `9 (EBADF)`

  Bad file number

- `10 (ECHILD)`

  No child processes

- `11 (EAGAIN)`

Try again

- `12 (ENOMEM)`

  Out of memory

- `13 (EACCES)`

  Permission denied

- `14 (EFAULT)`

  Bad address

- `15 (ENOTBLK)`

  Block device required

- `16 (EBUSY)`

  Device or resource busy

- `17 (EEXIST)`

  File exists

- `18 (EXDEV)`

  Cross-device link

- `19 (ENODEV)`

  No such device

- `20 (ENOTDIR)`

  Not a directory

- `21 (EISDIR)`

  Is a directory

- `22 (EINVAL)`

  Invalid argument

- `23 (ENFILE)`

  File table overflow

- `24 (EMFILE)`

  Too many open files

- `25 (ENOTTY)`

  Inappropriate ioctl for device

- `26 (ETXTBSY)`

  Text file busy

- `27 (EFBIG)`

File too large

- `28 (ENOSPC)`

  No space left on device

- `29 (ESPIPE)`

  Illegal seek

- `30 (EROFS)`

  Read-only file system

- `31 (EMLINK)`

  Too many links

The following table provides a list of some common Windows system error codes. For a complete list see the Microsoft Web site [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/debug/base/system_error_codes.asp].

- `1 (ERROR_INVALID_FUNCTION)`

  Incorrect function.

- `2 (ERROR_FILE_NOT_FOUND)`

  The system cannot find the file specified.

- `3 (ERROR_PATH_NOT_FOUND)`

  The system cannot find the path specified.

- `4 (ERROR_TOO_MANY_OPEN_FILES)`

  The system cannot open the file.

- `5 (ERROR_ACCESS_DENIED)`

  Access is denied.

- `6 (ERROR_INVALID_HANDLE)`

  The handle is invalid.

- `7 (ERROR_ARENA_TRASHED)`

  The storage control blocks were destroyed.

- `8 (ERROR_NOT_ENOUGH_MEMORY)`

  Not enough storage is available to process this command.

- `9 (ERROR_INVALID_BLOCK)`

  The storage control block address is invalid.

- `10 (ERROR_BAD_ENVIRONMENT)`

  The environment is incorrect.

- `11 (ERROR_BAD_FORMAT)`

  An attempt was made to load a program with an incorrect format.

- `12 (ERROR_INVALID_ACCESS)`

  The access code is invalid.

- `13 (ERROR_INVALID_DATA)`

  The data is invalid.

- `14 (ERROR_OUTOFMEMORY)`

  Not enough storage is available to complete this operation.

- `15 (ERROR_INVALID_DRIVE)`

  The system cannot find the drive specified.

- `16 (ERROR_CURRENT_DIRECTORY)`

  The directory cannot be removed.

- `17 (ERROR_NOT_SAME_DEVICE)`

  The system cannot move the file to a different disk drive.

- `18 (ERROR_NO_MORE_FILES)`

  There are no more files.

- `19 (ERROR_WRITE_PROTECT)`

  The media is write protected.

- `20 (ERROR_BAD_UNIT)`

  The system cannot find the device specified.

- `21 (ERROR_NOT_READY)`

  The device is not ready.

- `22 (ERROR_BAD_COMMAND)`

  The device does not recognize the command.

- `23 (ERROR_CRC)`

  Data error (cyclic redundancy check).

- `24 (ERROR_BAD_LENGTH)`

  The program issued a command but the command length is incorrect.

- `25 (ERROR_SEEK)`

  The drive cannot locate a specific area or track on the disk.

- `26 (ERROR_NOT_DOS_DISK)`

  The specified disk or diskette cannot be accessed.

- `27 (ERROR_SECTOR_NOT_FOUND)`

The drive cannot find the sector requested.

- `28 (ERROR_OUT_OF_PAPER)`

  The printer is out of paper.

- `29 (ERROR_WRITE_FAULT)`

  The system cannot write to the specified device.

- `30 (ERROR_READ_FAULT)`

  The system cannot read from the specified device.

- `31 (ERROR_GEN_FAILURE)`

  A device attached to the system is not functioning.

- `32 (ERROR_SHARING_VIOLATION)`

  The process cannot access the file because it is being used by another process.

- `33 (ERROR_LOCK_VIOLATION)`

  The process cannot access the file because another process has locked a portion of the file.

- `34 (ERROR_WRONG_DISK)`

  The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.

- `36 (ERROR_SHARING_BUFFER_EXCEEDED)`

  Too many files opened for sharing.

- `38 (ERROR_HANDLE_EOF)`

  Reached the end of the file.

- `39 (ERROR_HANDLE_DISK_FULL)`

  The disk is full.

- `87 (ERROR_INVALID_PARAMETER)`

  The parameter is incorrect. (If this error occurs on Windows and you have enabled `innodb_file_per_table` in a server option file, add the line `innodb_flush_method=unbuffered` to the file as well.)

- `112 (ERROR_DISK_FULL)`

  The disk is full.

- `123 (ERROR_INVALID_NAME)`

  The filename, directory name, or volume label syntax is incorrect.

- `1450 (ERROR_NO_SYSTEM_RESOURCES)`

  Insufficient system resources exist to complete the requested service.

15.2.16. Restrictions on `InnoDB` Tables

- **Warning:** Do *not* convert MySQL system tables in the `mysql` database from `MyISAM` to `InnoDB` tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the `mysql_install_db` script.

- A table cannot contain more than 1000 columns.

- The internal maximum key length is 3500 bytes, but MySQL itself restricts this to 1024 bytes.

- The maximum row length, except for `VARCHAR`, `BLOB` and `TEXT` columns, is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including also `BLOB` and `TEXT` columns, must be less than 4GB. `InnoDB` stores the first 768 bytes of a `VARCHAR`, `BLOB`, or `TEXT` column in the row, and the rest into separate pages.

- Although `InnoDB` supports row sizes larger than 65535 internally, you cannot define a row containing `VARCHAR` columns with a combined size larger than 65535:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
    -> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
    -> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

- On some older operating systems, files must be less than 2GB. This is not a limitation of `InnoDB` itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.

- The combined size of the `InnoDB` log files must be less than 4GB.

- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.

- `InnoDB` tables do not support `FULLTEXT` indexes.

- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by doing eight random dives to each of the index trees and updating index cardinality estimates accordingly. Note that because these are only estimates, repeated runs of `ANALYZE TABLE` may produce different numbers. This makes `ANALYZE TABLE` fast on `InnoDB` tables but not 100% accurate as it doesn't take all rows into account.

  MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` doesn't produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section 5.3.3, “Server System Variables”, and Section A.6, “Optimizer-Related Issues”.

- `SHOW TABLE STATUS` does not give accurate statistics on `InnoDB` tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- `InnoDB` does not keep an internal count of rows in a table. (In practice, this would be somewhat complicated due to multi-versioning.) To process a `SELECT COUNT(*) FROM t` statement, `InnoDB` must scan an index of the table, which takes some time if the index is not entirely in the buffer pool. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If your table does not change often, using the MySQL query cache is a good solution. `SHOW TABLE STATUS` also can be used if an approximate row count is sufficient. See Section 15.2.11, “`InnoDB` Performance Tuning Tips”.

- On Windows, `InnoDB` always stores database and table names internally in lowercase. To

move databases in binary format from Unix to Windows or from Windows to Unix, you should always use explicitly lowercase names when creating databases and tables.

- For an AUTO_INCREMENT column, you must always define an index for the table, and that index must contain just the AUTO_INCREMENT column. In MyISAM tables, the AUTO_INCREMENT column may be part of a multi-column index.

- When you restart the MySQL server, InnoDB may reuse an old value that was generated for an AUTO_INCREMENT column but never stored (that is, a value that was generated during an old transaction that was rolled back).

- When an AUTO_INCREMENT column runs out of values, InnoDB wraps a BIGINT to -9223372036854775808 and BIGINT UNSIGNED to 1. However, BIGINT values have 64 bits, so do note that if you were to insert one million rows per second, it would still take nearly three hundred thousand years before BIGINT reached its upper bound. With all other integer type columns, a duplicate-key error results. This is similar to how MyISAM works, because it is mostly general MySQL behavior and not about any storage engine in particular.

- DELETE FROM *tbl_name* does not regenerate the table but instead deletes all rows, one by one.

- Under some conditions, TRUNCATE *tbl_name* for an InnoDB table is mapped to DELETE FROM *tbl_name* and doesn't reset the AUTO_INCREMENT counter. See Section 13.2.9, "TRUNCATE Syntax".

- In MySQL 5.1, the MySQL LOCK TABLES operation acquires two locks on each table if innodb_table_locks=1 (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Older versions of MySQL did not acquire InnoDB table locks; the old behavior can be selected by setting innodb_table_locks=0. If no InnoDB table lock is acquired, LOCK TABLES completes even if some records of the tables are being locked by other transactions.

- All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke LOCK TABLES on InnoDB tables in AUTOCOMMIT=1 mode, because the acquired InnoDB table locks would be released immediately.

- Sometimes it would be useful to lock further tables in the course of a transaction. Unfortunately, LOCK TABLES in MySQL performs an implicit COMMIT and UNLOCK TABLES. An InnoDB variant of LOCK TABLES has been planned that can be executed in the middle of a transaction.

- The LOAD TABLE FROM MASTER statement for setting up replication slave servers does not yet work for InnoDB tables. A workaround is to alter the table to MyISAM on the master, do then the load, and after that alter the master table back to InnoDB. Do not do this if the tables use InnoDB-specific features such as foreign keys.

- The default database page size in InnoDB is 16KB. By recompiling the code, you can set it to values ranging from 8KB to 64KB. You must update the values of UNIV_PAGE_SIZE and UNIV_PAGE_SIZE_SHIFT in the univ.i source file.

- Currently, triggers are not activated by cascaded foreign key actions.

15.2.17. InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, you should look at the MySQL server error log, which is the file in the data directory that has a suffix of .err.

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through the mysqld_safe wrapper or as a Windows service. You can then see what mysqld prints to the console, and so have a better grasp of what is going on. On Win-

dows, you must start the server with the `--console` option to direct the output to the console window.

- Use the `InnoDB` Monitors to obtain information about a problem (see Section 15.2.11.1, "`SHOW ENGINE INNODB STATUS` and the `InnoDB` Monitors"). If the problem is performance-related, or your server appears to be hung, you should use `innodb_monitor` to print information about the internal state of `InnoDB`. If the problem is with locks, use `innodb_lock_monitor`. If the problem is in creation of tables or other data dictionary operations, use `innodb_table_monitor` to print the contents of the `InnoDB` internal data dictionary.

- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

15.2.17.1. Troubleshooting `InnoDB` Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in `.frm` files it stores in the database directories, whereas `InnoDB` also stores the information into its own data dictionary inside the tablespace files. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, the locations of the `.frm` files may end up out of sync with the locations recorded in the `InnoDB` internal data dictionary.

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, you should look in the server's error log. If the log says that the table already exists inside the `InnoDB` internal data dictionary, you have an orphaned table inside the `InnoDB` tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this, start the `mysql` client with the `--disable-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphaned `.frm` file by deleting it manually.

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the `InnoDB` tablespace. Using `innodb_table_monitor` you can see listed a table whose name is `#sql-...`. You can perform SQL statements on tables whose name con-

tains the character '#' if you enclose the name within backticks. Thus, you can drop such an orphaned table like any other orphaned table using the method described earlier. Note that to copy or rename a file in the Unix shell, you need to put the file name in double quotes if the file name contains '#'.

15.3. The MERGE Storage Engine

The MERGE storage engine, also known as the MRG_MyISAM engine, is a collection of identical MyISAM tables that can be used as one. "Identical" means that all tables have identical column and index information. You cannot merge tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the tables can be compressed with myisampack. See Section 8.2, "myisampack — Generate Compressed, Read-Only MyISAM Tables". Differences in table options such as AVG_ROW_LENGTH, MAX_ROWS, or PACK_KEYS do not matter.

When you create a MERGE table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table definition, and an .MRG file contains the names of the tables that should be used as one. The tables do not have to be in the same database as the MERGE table itself.

You can use SELECT, DELETE, UPDATE, and INSERT on the collection of tables. You must have SELECT, UPDATE, and DELETE privileges on the tables that you map to a MERGE table.

If you DROP the MERGE table, you are dropping only the MERGE specification. The underlying tables are not affected.

When you create a MERGE table, you must specify a UNION=(*list-of-tables*) clause that indicates which tables you want to use as one. You can optionally specify an INSERT_METHOD option if you want inserts for the MERGE table to take place in the first or last table of the UNION list. Use a value of FIRST or LAST to cause inserts to be made in the first or last table, respectively. If you do not specify an INSERT_METHOD option or if you specify it with a value of NO, attempts to insert records into the MERGE table result in an error.

The following example shows how to create a MERGE table:

```
mysql> CREATE TABLE t1 (
    ->    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->    message CHAR(20));
mysql> CREATE TABLE t2 (
    ->    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->    message CHAR(20));
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
    ->    a INT NOT NULL AUTO_INCREMENT,
    ->    message CHAR(20), INDEX(a))
    ->    ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Note that the a column is indexed in the MERGE table, but is not declared as a PRIMARY KEY as it is in the underlying MyISAM tables. This is necessary because a MERGE table cannot enforce uniqueness over the set of underlying tables.

After creating the MERGE table, you can issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+---------+
| a | message |
+---+---------+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
```

```
+---+---------+
```

Note that you can also manipulate the `.MRG` file directly from outside of the MySQL server:

```
shell> cd /mysql-data-directory/current-database
shell> ls -1 t1 t2 > total.MRG
shell> mysqladmin flush-tables
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can perform one of the following:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.
- Change the `.MRG` file and issue a `FLUSH TABLE` statement for the `MERGE` table and all underlying tables to force the storage engine to read the new definition file.

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a big read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table on this could be much faster than using the big table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the split tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (Note that you must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)
- If you have a set of tables that you join as a big table on demand or batch, you should instead create a `MERGE` table on them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.
- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- You cannot use a number of `MyISAM` features in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can, of course, create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)
- If the `MERGE` table is non-temporary, all underlying `MyISAM` tables have to be permanent, too.

If the MERGE table is temporary, the MyISAM tables can be any mix of temporary and non-temporary.

- MERGE tables use more file descriptors. If 10 clients are using a MERGE table that maps to 10 tables, the server uses (10*10) + 10 file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Key reads are slower. When you read a key, the MERGE storage engine needs to issue a read on all underlying tables to check which one most closely matches the given key. If you then do a read-next, the MERGE storage engine needs to search the read buffers to find the next key. Only when one key buffer is used up does the storage engine need to read the next key block. This makes MERGE keys much slower on eq_ref searches, but not much slower on ref searches. See Section 7.2.1, "EXPLAIN Syntax (Get Information About a SELECT)", for more information about eq_ref and ref.

15.3.1. MERGE Table Problems

The following are known problems with MERGE tables:

- If you use ALTER TABLE to change a MERGE table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying MyISAM tables are copied into the altered table, which is then assigned the new type.
- REPLACE does not work.
- You cannot use DROP TABLE, ALTER TABLE, DELETE FROM without a WHERE clause, REPAIR TABLE, TRUNCATE TABLE, OPTIMIZE TABLE, or ANALYZE TABLE on any of the tables that are mapped into an open MERGE table. If you do so, the MERGE table may still refer to the original table, which yields unexpected results. The easiest way to work around this deficiency is to issue a FLUSH TABLES statement prior to performing any of these operations to ensure that no MERGE tables remain open.
- A MERGE table cannot maintain UNIQUE constraints over the whole table. When you perform an INSERT, the data goes into the first or last MyISAM table (depending on the value of the INSERT_METHOD option). MySQL ensures that unique key values remain unique within that MyISAM table, but not across all the tables in the collection.
- When you create a MERGE table, there is no check to insure that the underlying tables exist and have identical structures. When the MERGE table is used, MySQL checks that the record length for all mapped tables is equal, but this is not foolproof. If you create a MERGE table from dissimilar MyISAM tables, you are very likely to run into strange problems.
- The order of indexes in the MERGE table and its underlying tables should be the same. If you use ALTER TABLE to add a UNIQUE index to a table used in a MERGE table, and then use ALTER TABLE to add a non-unique index on the MERGE table, the index ordering is different for the tables if there was already a non-unique index in the underlying table. (This happens because ALTER TABLE puts UNIQUE indexes before non-unique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- DROP TABLE on a table that is in use by a MERGE table does not work on Windows because the MERGE storage engine's table mapping is hidden from the upper layer of MySQL. Since Windows does not allow the deletion of open files, you first must flush all MERGE tables (with FLUSH TABLES) or drop the MERGE table before dropping the table.

Additional resources

- For the MERGE storage engine, there's a dedicated forum available on http://forums.mysql.com/list.php?93.

15.4. The MEMORY (HEAP) Storage Engine

The MEMORY storage engine creates tables with contents that are stored in memory. These were formerly known as HEAP tables. MEMORY is the preferred term, although HEAP remains supported for backward compatibility.

Each MEMORY table is associated with one disk file. The filename begins with the table name and has an extension of .frm to indicate that it stores the table definition.

To specify explicitly that you want a MEMORY table, indicate that with an ENGINE option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by their name, MEMORY tables are stored in memory and use hash indexes by default. This makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all data stored in MEMORY tables is lost. The tables themselves continue to exist because their definitions are stored in .frm files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a MEMORY table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
    ->     SELECT ip,SUM(downloads) AS down
    ->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

MEMORY tables have the following characteristics:

- Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

- MEMORY tables can have up to 32 indexes per table, 16 columns per index and a maximum key length of 500 bytes.

- The MEMORY storage engine implements both HASH and BTREE indexes. You can specify one or the other for a given index by adding a USING clause as shown here:

  ```
  CREATE TABLE lookup
      (id INT, INDEX USING HASH (id))
      ENGINE = MEMORY;
  CREATE TABLE lookup
      (id INT, INDEX USING BTREE (id))
      ENGINE = MEMORY;
  ```

  General characteristics of B-tree and hash indexes are described in Section 7.4.5, “How MySQL Uses Indexes”.

- You can have non-unique keys in a MEMORY table. (This is an uncommon feature for implementations of hash indexes.)

- You can also use INSERT DELAYED with MEMORY tables. See Section 13.2.4.2, “INSERT DELAYED Syntax”.

- If you have a hash index on a MEMORY table that has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a BTREE index to avoid this problem.

- MEMORY tables use a fixed record length format.
- MEMORY doesn't support BLOB or TEXT columns.
- MEMORY includes support for both AUTO_INCREMENT columns and indexes on columns that can contain NULL values.
- MEMORY tables are shared between all clients (just like any other non-TEMPORARY table).
- MEMORY table contents are stored in memory, which is a property that MEMORY tables share with internal tables that the server creates on the fly while processing queries. However, the two types of tables differ in that MEMORY tables are not subject to storage conversion, whereas internal tables are:
  - If an internal table becomes too large, the server automatically converts it to an on-disk table. The size limit is determined by the value of the tmp_table_size system variable.
  - MEMORY tables are never converted to disk tables. To ensure that you don't accidentally do anything foolish, you can set the max_heap_table_size system variable to impose a maximum size on MEMORY tables. For individual tables, you can also specify a MAX_ROWS table option in the CREATE TABLE statement.
- The server needs sufficient memory to maintain all MEMORY tables that are in use at the same time.
- To free memory used by a MEMORY table when you no longer require its contents, you should execute DELETE FROM or TRUNCATE TABLE, or remove the table altogether (using DROP TABLE).
- If you want to populate a MEMORY table when the MySQL server starts, you can use the --init-file option. For example, you can put statements such as INSERT INTO ... SELECT or LOAD DATA INFILE into this file in order to load the table from a persistent data source. See Section 5.3.1, "mysqld Command-Line Options", and Section 13.2.5, "LOAD DATA INFILE Syntax".
- If you are using replication, the master server's MEMORY tables become empty when it is shut down and restarted. However, a slave is not aware that these tables have become empty, so it returns out-of-date content if you select data from them. When a MEMORY table is used on the master for the first time since the master was started, a DELETE FROM statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has outdated data in the table during the interval between the master's restart and its first use of the table. However, if you use the --init-file option to populate the MEMORY table on the master at startup, it ensures that this time interval is zero.
- The memory needed for one row in a MEMORY table is calculated using the following expression:

  ```
  SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
  + SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
  + ALIGN(length_of_row+1, sizeof(char*))
  ```

  ALIGN() represents a round-up factor to cause the row length to be an exact multiple of the char pointer size. sizeof(char*) is 4 on 32-bit machines and 8 on 64-bit machines.

- For the MEMORY storage engine, there's a dedicated forum available on http://forums.mysql.com/list.php?92.

15.5. The BDB (BerkeleyDB) Storage Engine

Sleepycat Software has provided MySQL with the Berkeley DB transactional storage engine. This storage engine typically is called BDB for short. Support for the BDB storage engine is included in MySQL source distributions is activated in MySQL-Max binary distributions.

BDB tables may have a greater chance of surviving crashes and are also capable of COMMIT and ROLLBACK operations on transactions. The MySQL source distribution comes with a BDB distribution that is patched to make it work with MySQL. You cannot use a non-patched version of BDB with MySQL.

We at MySQL AB work in close cooperation with Sleepycat to keep the quality of the MySQL/BDB interface high. (Even though Berkeley DB is in itself very tested and reliable, the MySQL interface is still considered gamma quality. We continue to improve and optimize it.)

When it comes to support for any problems involving BDB tables, we are committed to helping our users locate the problem and create reproducible test cases. Any such test case is forwarded to Sleepycat, who in turn help us find and fix the problem. As this is a two-stage operation, any problems with BDB tables may take a little longer for us to fix than for other storage engines. However, we anticipate no significant difficulties with this procedure because the Berkeley DB code itself is used in many applications other than MySQL.

For general information about Berkeley DB, please visit the Sleepycat Web site, http://www.sleepycat.com/.

15.5.1. Operating Systems Supported by BDB

Currently, we know that the BDB storage engine works with the following operating systems:

- Linux 2.x Intel
- Sun Solaris (SPARC and x86)
- FreeBSD 4.x/5.x (x86, sparc64)
- IBM AIX 4.3.x
- SCO OpenServer
- SCO UnixWare 7.1.x
- Windows NT/2000/XP

BDB does *not* work with the following operating systems:

- Linux 2.x Alpha
- Linux 2.x AMD64
- Linux 2.x IA-64
- Linux 2.x s390
- Mac OS X

Note: The preceding lists are not complete. We update them as we receive more information.

If you build MySQL from source with support for BDB tables, but the following error occurs when you start mysqld, it means BDB is not supported for your architecture:

```
bdb: architecture lacks fast mutexes: applications cannot be threaded
Can't init databases
```

In this case, you must rebuild MySQL without BDB table support or start the server with the `--skip-bdb` option.

15.5.2. Installing BDB

If you have downloaded a binary version of MySQL that includes support for Berkeley DB, simply follow the usual binary distribution installation instructions. (MySQL-Max distributions include BDB support.)

If you build MySQL from source, you can enable BDB support by running `configure` with the `--with-berkeley-db` option in addition to any other options that you normally use. Download a MySQL 5.1 distribution, change location into its top-level directory, and run this command:

```
shell> ./configure --with-berkeley-db [other-options]
```

For more information, see Section 2.7, “Installing MySQL on Other Unix-Like Systems”, Section 5.1.2, “The `mysqld-max` Extended MySQL Server”, and Section 2.8, “MySQL Installation Using a Source Distribution”.

15.5.3. BDB Startup Options

The following options to `mysqld` can be used to change the behavior of the BDB storage engine:

- `--bdb-data-direct`

  Turn off system buffering of BDB database files to avoid double caching. This option was added in MySQL 5.1.4.

- `--bdb-home=`*`path`*

  The base directory for BDB tables. This should be the same directory you use for `--datadir`.

- `--bdb-lock-detect=`*`method`*

  The BDB lock detection method. The option value should be DEFAULT, OLDEST, RANDOM, YOUNGEST, MAXLOCKS, MINLOCKS, MAXWRITE, or MINWRITE.

- `--bdb-log-direct`

  Turn off system buffering of BDB log files to avoid double caching. This option was added in MySQL 5.1.4.

- `--bdb-logdir=`*`path`*

  The BDB log file directory.

- `--bdb-no-recover`

  Do not start Berkeley DB in recover mode.

- `--bdb-no-sync`

  Don't synchronously flush the BDB logs. This option is deprecated; use `--skip-sync-bdb-logs` instead (see the description for `--sync-bdb-logs`).

- `--bdb-shared-data`

Start Berkeley DB in multi-process mode. (Do not use `DB_PRIVATE` when initializing Berkeley DB.)

- `--bdb-tmpdir=`*`path`*

  The `BDB` temporary file directory.

- `--skip-bdb`

  Disable the `BDB` storage engine.

- `--sync-bdb-logs`

  Synchronously flush the `BDB` logs. This option is enabled by default; use `--skip-sync-bdb-logs` to disable it.

See Section 5.3.1, "`mysqld` Command-Line Options".

If you use the `--skip-bdb` option, MySQL does not initialize the Berkeley DB library and this saves a lot of memory. However, if you use this option, you cannot use `BDB` tables. If you try to create a `BDB` table, MySQL creates a `MyISAM` table instead.

Normally, you should start `mysqld` without the `--bdb-no-recover` option if you intend to use `BDB` tables. However, this may cause problems when you try to start `mysqld` if the `BDB` log files are corrupted. See Section 2.9.2.3, "Starting and Troubleshooting the MySQL Server".

With the `bdb_max_lock` variable, you can specify the maximum number of locks that can be active on a `BDB` table. The default is 10,000. You should increase this if errors such as the following occur when you perform long transactions or when `mysqld` has to examine many rows to execute a query:

```
bdb: Lock table is out of available locks
Got error 12 from ...
```

You may also want to change the `binlog_cache_size` and `max_binlog_cache_size` variables if you are using large multiple-statement transactions. See Section 5.11.3, "The Binary Log".

See also Section 5.3.3, "Server System Variables".

15.5.4. Characteristics of BDB Tables

Each `BDB` table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table definition, and a `.db` file contains the table data and indexes.

To specify explicitly that you want a `BDB` table, indicate that with an `ENGINE` or `TYPE` table option:

```
CREATE TABLE t (i INT) ENGINE = BDB;
CREATE TABLE t (i INT) TYPE = BDB;
```

`BerkeleyDB` is a synonym for `BDB` in the `ENGINE` or `TYPE` option.

The `BDB` storage engine provides transactional tables. The way you use these tables depends on the autocommit mode:

- If you are running with autocommit enabled (which is the default), changes to `BDB` tables are committed immediately and cannot be rolled back.

- If you are running with autocommit disabled, changes do not become permanent until you execute a `COMMIT` statement. Instead of committing, you can execute `ROLLBACK` to forget the changes.

  You can start a transaction with the `BEGIN WORK` statement to suspend autocommit, or with `SET AUTOCOMMIT=0` to disable autocommit explicitly.

See Section 13.4.1, "`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax".

The `BDB` storage engine has the following characteristics:

- `BDB` tables can have up to 31 indexes per table, 16 columns per index, and a maximum key size of 1024 bytes.
- MySQL requires a `PRIMARY KEY` in each `BDB` table so that each row can be uniquely identified. If you don't create one explicitly, MySQL creates and maintains a hidden `PRIMARY KEY` for you. The hidden key has a length of five bytes and is incremented for each insert attempt. This key does not appear in the output of `SHOW CREATE TABLE` or `DESCRIBE`.
- The `PRIMARY KEY` is faster than any other index, because the `PRIMARY KEY` is stored together with the row data. The other indexes are stored as the key data + the `PRIMARY KEY`, so it's important to keep the `PRIMARY KEY` as short as possible to save disk space and get better speed.

  This behavior is similar to that of `InnoDB`, where shorter primary keys save space not only in the primary index but in secondary indexes as well.
- If all columns you access in a `BDB` table are part of the same index or part of the primary key, MySQL can execute the query without having to access the actual row. In a `MyISAM` table, this can be done only if the columns are part of the same index.
- Sequential scanning is slower than for `MyISAM` tables because the data in `BDB` tables is stored in B-trees and not in a separate data file.
- Key values are not prefix- or suffix-compressed like key values in `MyISAM` tables. In other words, key information takes a little more space in `BDB` tables compared to `MyISAM` tables.
- There are often holes in the `BDB` table to allow you to insert new rows in the middle of the index tree. This makes `BDB` tables somewhat larger than `MyISAM` tables.
- `SELECT COUNT(*) FROM` *`tbl_name`* is slow for `BDB` tables, because no row count is maintained in the table.
- The optimizer needs to know the approximate number of rows in the table. MySQL solves this by counting inserts and maintaining this in a separate segment in each `BDB` table. If you don't issue a lot of `DELETE` or `ROLLBACK` statements, this number should be accurate enough for the MySQL optimizer. However, MySQL stores the number only on close, so it may be incorrect if the server terminates unexpectedly. It should not be fatal even if this number is not 100% correct. You can update the row count by using `ANALYZE TABLE` or `OPTIMIZE TABLE`. See Section 13.5.2.1, "`ANALYZE TABLE` Syntax", and Section 13.5.2.5, "`OPTIMIZE TABLE` Syntax".
- Internal locking in `BDB` tables is done at the page level.
- `LOCK TABLES` works on `BDB` tables as with other tables. If you do not use `LOCK TABLES`, MySQL issues an internal multiple-write lock on the table (a lock that does not block other writers) to ensure that the table is properly locked if another thread issues a table lock.
- To be able to roll back transactions, the `BDB` storage engine maintains log files. For maximum performance, you can use the `--bdb-logdir` option to place the `BDB` logs on a different disk than the one where your databases are located.

- MySQL performs a checkpoint each time a new BDB log file is started, and removes any BDB log files that are not needed for current transactions. You can also use FLUSH LOGS at any time to checkpoint the Berkeley DB tables.

  For disaster recovery, you should use table backups plus MySQL's binary log. See Section 5.9.1, “Database Backups”.

  Warning: If you delete old log files that are still in use, BDB is not able to do recovery at all and you may lose data if something goes wrong.

- Applications must always be prepared to handle cases where any change of a BDB table may cause an automatic rollback and any read may fail with a deadlock error.

- If you get a full disk with a BDB table, you get an error (probably error 28) and the transaction should roll back. This contrasts with MyISAM tables, for which mysqld waits for sufficient free disk space before continuing.

15.5.5. Things We Need to Fix for BDB

- Opening many BDB tables at the same time may be quite slow. If you are going to use BDB tables, you should not have a very large table cache (for example, with a size larger than 256) and you should use the --no-auto-rehash option when you use the mysql client.

- SHOW TABLE STATUS does not provide some information for BDB tables:

```
mysql> SHOW TABLE STATUS LIKE 'bdbtest'\G
*************************** 1. row ***************************
           Name: bdbtest
         Engine: BerkeleyDB
        Version: 10
     Row_format: Dynamic
           Rows: 154
 Avg_row_length: 0
    Data_length: 0
Max_data_length: 0
   Index_length: 0
      Data_free: 0
 Auto_increment: NULL
    Create_time: NULL
    Update_time: NULL
     Check_time: NULL
      Collation: latin1_swedish_ci
       Checksum: NULL
 Create_options:
        Comment:
```

- Optimize performance.

- Change to use no page locks for table scanning operations.

15.5.6. Restrictions on BDB Tables

The following list indicates restrictions that you must observe when using BDB tables:

- Each BDB table stores in the .db file the path to the file as it was created. This was done enable detection of locks in a multi-user environment that supports symlinks. As a consequence of this, it is not possible to move BDB table files from one database directory to another.

- When making backups of BDB tables, you must either use mysqldump or else make a backup

that includes the files for each BDB table (the .frm and .db files) as well as the BDB log files. The BDB storage engine stores unfinished transactions in its log files and requires them to be present when mysqld starts. The BDB logs are the files in the data directory with names of the form log.XXXXXXXXXX (ten digits).

- If a column that allows NULL values has a unique index, only a single NULL value is allowed. This differs from other storage engines.

15.5.7. Errors That May Occur When Using BDB Tables

- If the following error occurs when you start mysqld after upgrading, it means that the new BDB version doesn't support the old log file format:

```
bdb:  Ignoring log file: .../log.XXXXXXXXXX:
unsupported log version #
```

  In this case, you must delete all BDB logs from your data directory (the files with names that have the format log.XXXXXXXXXX) and restart mysqld. We also recommend that you then use mysqldump --opt to dump your BDB tables, drop the tables, and restore them from the dump file.

- If autocommit mode is disabled and you drop a BDB table that is referenced in another transaction, you may get error messages of the following form in your MySQL error log:

```
001119 23:43:56  bdb:  Missing log fileid entry
001119 23:43:56  bdb:  txn_abort: Log undo failed for LSN:
                      1 3644744: Invalid
```

  This is not fatal, but until the problem is fixed, we recommend that you not drop BDB tables except while autocommit mode is enabled. (The fix is not trivial.)

15.6. The EXAMPLE Storage Engine

The EXAMPLE storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To examine the source for the EXAMPLE engine, look in the sql/examples directory of a MySQL source distribution.

To enable this storage engine, use the --with-example-storage-engine option to configure when you build MySQL.

When you create an EXAMPLE table, the server creates a table definition file in the database directory. The file begins with the table name and has an .frm extension. No other files are created. No data can be stored into the table or retrieved from it.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The EXAMPLE storage engine does not support indexing.

15.7. The FEDERATED Storage Engine

The FEDERATED storage engine accesses data in tables of remote databases rather than in local tables.

The FEDERATED storage engine is available only in the -Max version of MySQL.

To examine the source for the FEDERATED engine, look in the sql directory of a MySQL source distribution.

Additional resources

- For the FEDERATED storage engine, there's a dedicated forum available on http://forums.mysql.com/list.php?105.

15.7.1. Installing the FEDERATED Storage Engine

To enable this storage engine, use the --with-federated-storage-engine option to configure when you build MySQL.

15.7.2. Description of the FEDERATED Storage Engine

When you create a FEDERATED table, the server creates a table definition file in the database directory. The file begins with the table name and has an .frm extension. No other files are created, because the actual data is in a remote database. This differs from the way that storage engines for local tables work.

For local database tables, data files are local. For example, if you create a MyISAM table named users, the MyISAM handler creates a data file named users.MYD. A handler for local tables reads, inserts, deletes, and updates data in local data files, and records are stored in a format particular to the handler. To read records, the handler must parse data into columns. To write records, column values must be converted to the row format used by the handler and written to the local data file.

With the MySQL FEDERATED storage engine, there are no local data files for a table (for example, there is no .MYD file). Instead, a remote database stores the data that normally would be in the table. This necessitates the use of the MySQL client API to read, delete, update, and insert data. Data retrieval is initiated via a SELECT * FROM *tbl_name* SQL statement. To read the result, rows are fetched one at a time by using the mysql_fetch_row() C API function, and then converted from the columns in the SELECT result set to the format that the FEDERATED handler expects.

The basic flow is as follows:

1. SQL calls issued locally
2. MySQL handler API (data in handler format)
3. MySQL client API (data converted to SQL calls)
4. Remote database -> MySQL client API
5. Convert result sets (if any) to handler format
6. Handler API -> Result rows or rows-affected count to local

15.7.3. How to use FEDERATED Tables

The procedure for using FEDERATED tables is very simple. Normally, you have two servers run-

ning, either both on the same host or on different hosts. (It is also possible for a FEDERATED table to use another table that is managed by the same server, though there is little point in doing so.)

First, you must have a table on the remote server that you want to access with the FEDERATED table. Suppose that the remote table is in the federated database and is defined like this:

```
CREATE TABLE test_table (
    id     int(20) NOT NULL auto_increment,
    name   varchar(32) NOT NULL default '',
    other  int(20) NOT NULL default '0',
    PRIMARY KEY  (id),
    KEY name (name),
    KEY other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

The ENGINE table option could name any storage engine; the table need not be a MyISAM table.

Next, create a FEDERATED table on the local server for accessing the remote table:

```
CREATE TABLE federated_table (
    id     int(20) NOT NULL auto_increment,
    name   varchar(32) NOT NULL default '',
    other  int(20) NOT NULL default '0',
    PRIMARY KEY  (id),
    KEY name (name),
    KEY other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://root@remote_host:9306/federated/test_table';
```

(**Note**: CONNECTION replaces the COMMENT used in some previous versions of MySQL.)

The structure of this table must be exactly the same as that of the remote table, except that the ENGINE table option should be FEDERATED and the CONNECTION table option is a connection string that indicates to the FEDERATED engine how to connect to the remote server.

The FEDERATED engine creates only the test_table.frm file in the federated database.

The remote host information indicates the remote server to which your local server connects, and the database and table information indicates which remote table to use as the data file. In this example, the remote server is indicated to be running as remote_host on port 9306, so you want to start that server so that it listens to port 9306.

The general form of the connection string in the CONNECTION option is as follows:

scheme://*user_name*[:*password*]@*host_name*[:*port_num*]/*db_name*/*tbl_name*

Only mysql is supported as the *scheme* at this point; the password and port number are optional.

Here are some example connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

The use of CONNECTION for specifying the connection string is non-optimal and is likely to change in future. Keep this in mind when you use FEDERATED tables, because it means that modifications are likely to be required when that happens.

Because any password used is stored in the connection string as plain text, it can be seen by any user

who can use SHOW CREATE TABLE or SHOW TABLE STATUS for the FEDERATED table, or query the TABLES table in the INFORMATION_SCHEMA database.

Additional resources

- For the FEDERATED storage engine, there's a dedicated forum available on http://forums.mysql.com/list.php?105.

15.7.4. Limitations of the FEDERATED Storage Engine

What the FEDERATED storage engine does and does not support:

- In the first version, the remote server must be a MySQL server. Support by FEDERATED for other database engines may be added in the future.
- The remote table that a FEDERATED table points to *must* exist before you try to access the table through the FEDERATED table.
- It is possible for one FEDERATED table to point to another, but you must be careful not to create a loop.
- There is no support for transactions.
- There is no way for the FEDERATED engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database. The integrity of the data in the local table could be breached if there was any change to the remote database.
- The FEDERATED storage engine supports SELECT, INSERT, UPDATE, DELETE, and indexes. It does not support ALTER TABLE, DROP TABLE, or any other Data Definition Language statements. The current implementation does not use Prepared statements.
- The implementation uses SELECT, INSERT, UPDATE, and DELETE, but not HANDLER.
- FEDERATED tables do not work with the query cache.

Some of these limitations may be lifted in future versions of the FEDERATED handler.

15.8. The ARCHIVE Storage Engine

The ARCHIVE storage engine is used for storing large amounts of data without indexes in a very small footprint.

To enable this storage engine, use the --with-archive-storage-engine option to configure when you build MySQL. You can see if this storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_archive';
```

When you create an ARCHIVE table, the server creates a table definition file in the database directory. The file begins with the table name and has an .frm extension. The storage engine creates other files, all having names beginning with the table name. The data and metadata files have extensions of .ARZ and .ARM. A .ARN file may appear during optimization operations.

The ARCHIVE engine supports only INSERT and SELECT (no deletes, replaces, or updates). It does support ORDER BY operations, BLOB fields, and basically all data types except geometry data types (see Section 19.4.1, “MySQL Spatial Data Types”). The ARCHIVE engine uses row-level

locking.

Storage: Records are compressed as they are inserted. The ARCHIVE engine uses zlib [http://www.zlib.net/] lossless data compression. Use of OPTIMIZE TABLE can analyze the table and pack it into a smaller format (for a reason to use OPTIMIZE TABLE, see below). The engine also supports CHECK TABLE, too. There are several types of insertions that are used:

- A straight INSERT just pushes rows into a compression buffer, and that buffer flushes as it needs. The insertion into the buffer is protected by a lock. A SELECT forces a flush to occur, unless the only insertions that have come in were INSERT DELAYED (those flush as need be). See Section 13.2.4.2, "INSERT DELAYED Syntax".

- A bulk insert is only visible after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A SELECT never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, records are uncompressed on demand; there is no row cache. A SELECT operation performs a complete table scan: When a SELECT occurs, it finds out how many rows are currently available and reads that number of rows. SELECT is performed as a consistent read. Note that lots of SELECT statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To fix any compression issues that have occurred you can always do an OPTIMIZE TABLE (REPAIR TABLE also is supported). The number of rows in ARCHIVE tables reported by SHOW TABLE STATUS is always accurate. See Section 13.5.2.6, "REPAIR TABLE Syntax", Section 13.5.2.5, "OPTIMIZE TABLE Syntax", Section 13.5.4.18, "SHOW TABLE STATUS Syntax".

Additional resources

- For the ARCHIVE storage engine, there's a dedicated forum available on http://forums.mysql.com/list.php?112.

15.9. The CSV Storage Engine

The CSV storage engine stores data in text files using comma-separated values format.

To enable this storage engine, use the --with-csv-storage-engine option to configure when you build MySQL.

When you create a CSV table, the server creates a table definition file in the database directory. The file begins with the table name and has an .frm extension. The storage engine also creates a data file. Its name begins with the table name and has a .CSV extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in CSV format.

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
+------+------------+
| i    | c          |
+------+------------+
|    1 | record one |
|    2 | record two |
+------+------------+
2 rows in set (0.00 sec)
```

If you examine the test.CSV file in the database directory created by executing the preceding

statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

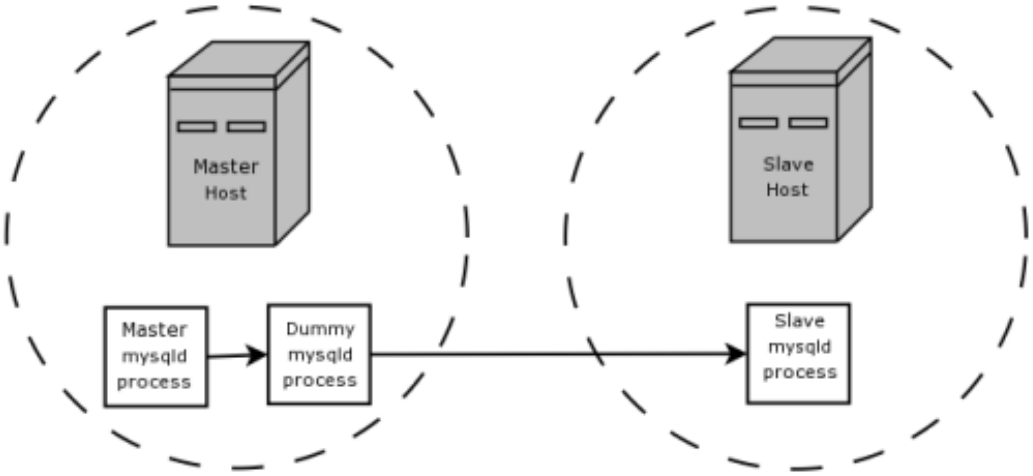
The CSV storage engine does not support indexing.

15.10. The BLACKHOLE Storage Engine

The BLACKHOLE storage engine acts as a "black hole" that accepts data but throws it away and does not store it. Retrievals always return the empty set:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0



mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

When you create a BLACKHOLE table, the server creates a table definition file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The BLACKHOLE storage engine supports all kinds of indexing.

To enable this storage engine, use the `--with-blackhole-storage-engine` option to `configure` when you build MySQL. The BLACKHOLE storage engine is available in MySQL-supplied server binaries; you can determine whether or not your version supports this engine by viewing the output of SHOW ENGINES or SHOW VARIABLES LIKE 'have%'.

Inserts into a BLACKHOLE table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. For example, suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a "dummy" slave process whose default storage engine is BLACKHOLE, depicted as follows:

The master writes to its binary log. The "dummy" `mysqld` process acts as a slave, applying the desired combination of `replicate-do` and `replicate-ignore` rules, and writes a new, filtered binary log of its own. (See Section 6.9, "Replication Startup Options".) This filtered log is provided to the slave.

Since the dummy process does not actually store any data, there is little processing over head incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

Other possible uses for the BLACKHOLE storage engine include:

- Verification of dumpfile syntax.
- Measurement of the overhead from binary logging, by comparing performance using BLACKHOLE with and without binary logging enabled.
- since BLACKHOLE is essentially a “no-op” storage engine, it could be used for finding performance bottlenecks not related to the storage engine itself.

As of MySQL 5.1.4, the BLACKHOLE engine is transaction-aware in the sense that committed transactions are written to the binary log, but rolled-back transactions are not.

Chapter 16. Writing a Custom Storage Engine

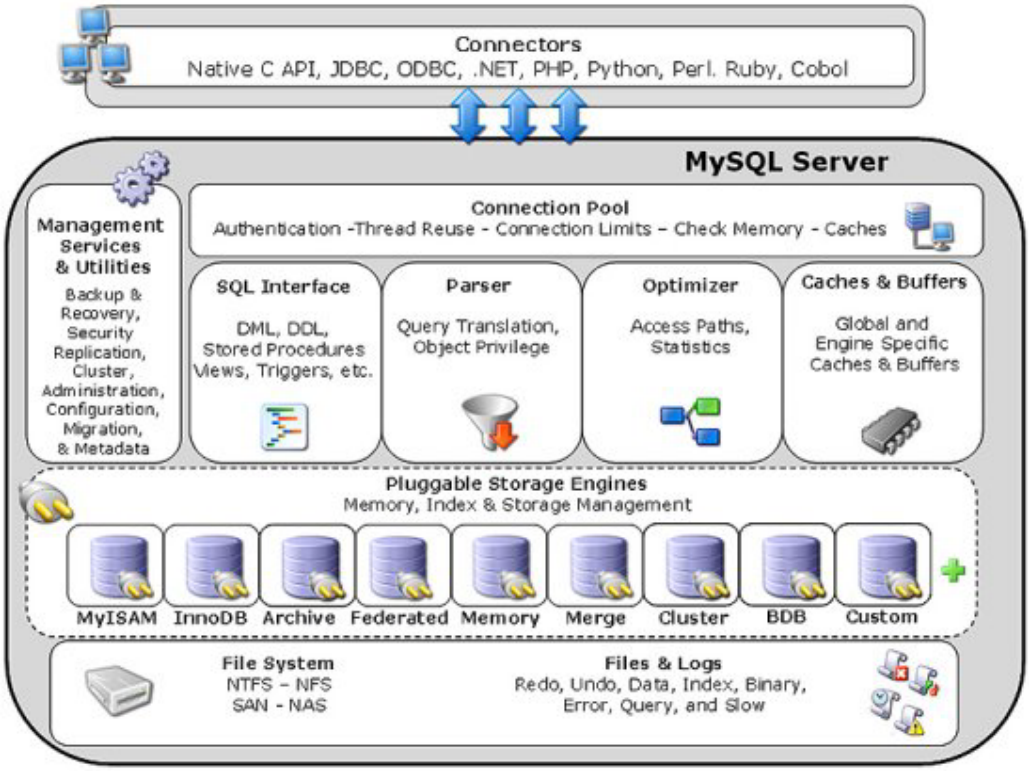
16.1. Introduction

With MySQL 5.1, MySQL AB has introduced a pluggable storage engine architecture that makes it possible to create new storage engines and add them to a running MySQL server without recompiling the server itself.

This architecture makes it easier to develop new storage engines for MySQL and deploy them.

This chapter is intended as a guide to assist you in developing a storage engine for the new pluggable storage engine architecture.

For more information on the MySQL pluggable storage engine architecture, see Chapter 14, *Pluggable Storage Engine Architecture*.



Additional resources

- There is a forum dedicated to custom storage engines available on http://forums.mysql.com/list.php?94.

16.2. Overview

The MySQL server is built in a modular fashion:

Figure 16.1. MySQL architecture

The storage engines manage data storage and index management for MySQL. The MySQL server communicates with the storage engines through a defined API.

Each storage engine is an class with each instance of the class communicating with the MySQL server through a special `handler` interface.

Handlers are instanced on the basis of one handler for each thread that needs to work with a specific table. For example: If three connections all start working with the same table, three handler instances will need to be created.

Once a handler instance is created, the MySQL server issues commands to the handler to perform data storage and retrieval tasks such as opening a table, manipulating rows, and managing indexes.

Custom storage engines can be built in a progressive manner: Developers can start with a read-only storage engine and later add support for `INSERT`, `UPDATE`, and `DELETE` operations, and even later add support for indexing, transactions, and other advanced operations.

16.3. Creating Storage Engine Source Files

The easiest way to implement a new storage engine is to begin by copying and modifying the `EXAMPLE` storage engine. The `ha_example.cc` and `ha_example.h` files can be found in the `sql/examples/` directory of the MySQL 5.1 source tree. For instructions how to obtain the 5.1 source tree, see Section 2.8.3, “Installing from the Development Source Tree”.

When copying the files, change the names from `ha_example.cc` and `ha_example.h` to something appropriate to your storage engine, such as `ha_foo.cc` and `ha_foo.h`.

After you have copied and renamed the files you must replace all instances of `EXAMPLE` and `example` with the name of your storage engine. If you are familiar with `sed`, these steps can be done automatically (in this example, the name of your storage engine would be “FOO”):

```
sed s/EXAMPLE/FOO/g ha_example.h | sed s/example/foo/g ha_foo.h
sed s/EXAMPLE/FOO/g ha_example.cc | sed s/example/foo/g ha_foo.cc
```

16.4. Creating the `handlerton`

The `handlerton` (short for “handler singleton”) defines the storage engine and contains function pointers to those functions that apply to the storage engine as a whole, as opposed to functions that work on a per-table basis. Some examples of such functions include transaction functions to handle commits and rollbacks.

Here's an example from the `EXAMPLE` storage engine:

```
handlerton example_hton= {
  "EXAMPLE",
  SHOW_OPTION_YES,
  "Example storage engine",
  DB_TYPE_EXAMPLE_DB,
  NULL,     /* Initialize */
  0,        /* slot */
  0,        /* savepoint size. */
  NULL,     /* close_connection */
  NULL,     /* savepoint */
  NULL,     /* rollback to savepoint */
  NULL,     /* release savepoint */
  NULL,     /* commit */
  NULL,     /* rollback */
  NULL,     /* prepare */
  NULL,     /* recover */
  NULL,     /* commit_by_xid */
  NULL,     /* rollback_by_xid */
  NULL,     /* create_cursor_read_view */
```

```
  NULL,    /* set_cursor_read_view */
  NULL,    /* close_cursor_read_view */
  example_create_handler,    /* Create a new handler */
  NULL,    /* Drop a database */
  NULL,    /* Panic call */
  NULL,    /* Release temporary latches */
  NULL,    /* Update Statistics */
  NULL,    /* Start Consistent Snapshot */
  NULL,    /* Flush logs */
  NULL,    /* Show status */
  NULL,    /* Replication Report Sent Binlog */
  HTON_CAN_RECREATE
};
```

This is the definition of the `handlerton` from `handler.h`:

```
typedef struct
  {
    const char *name;
    SHOW_COMP_OPTION state;
    const char *comment;
    enum db_type db_type;
    bool (*init)();
    uint slot;
    uint savepoint_offset;
    int  (*close_connection)(THD *thd);
    int  (*savepoint_set)(THD *thd, void *sv);
    int  (*savepoint_rollback)(THD *thd, void *sv);
    int  (*savepoint_release)(THD *thd, void *sv);
    int  (*commit)(THD *thd, bool all);
    int  (*rollback)(THD *thd, bool all);
    int  (*prepare)(THD *thd, bool all);
    int  (*recover)(XID *xid_list, uint len);
    int  (*commit_by_xid)(XID *xid);
    int  (*rollback_by_xid)(XID *xid);
    void *(*create_cursor_read_view)();
    void (*set_cursor_read_view)(void *);
    void (*close_cursor_read_view)(void *);
    handler *(*create)(TABLE *table);
    void (*drop_database)(char* path);
    int (*panic)(enum ha_panic_function flag);
    int (*release_temporary_latches)(THD *thd);
    int (*update_statistics)();
    int (*start_consistent_snapshot)(THD *thd);
    bool (*flush_logs)();
    bool (*show_status)(THD *thd, stat_print_fn *print, enum ha_stat_type stat)
    int (*repl_report_sent_binlog)(THD *thd, char *log_file_name, my_off_t end_
    uint32 flags;
  } handlerton;
```

There are a total of 30 handlerton elements, only a few of which are mandatory (specifically the first four elements and the `create()` function).

1. The name of the storage engine. This is the name that will be used when creating tables (`CREATE TABLE ... ENGINE = FOO;`).

2. The value to be displayed in the `status` field when a user issues the `SHOW STORAGE ENGINES` command.

3. The storage engine comment, a description of the storage engine displayed when using the `SHOW STORAGE ENGINES` command.

4. An integer that uniquely identifies the storage engine within the MySQL server. The constants used by the built-in storage engines are defined in the `handler.h` file. Custom engines should use `DB_TYPE_CUSTOM`.

5. A function pointer to the storage engine initializer. This function is only called once when the server starts to allow the storage engine class to perform any housekeeping that is necessary before handlers are instanced.

6. The slot. Each storage engine has its own memory area (actually a pointer) in the `thd`, for storing per-connection information. It is accessed as `thd->ha_data[foo_hton.slot]`. The slot number is initialized by MySQL after `foo_init()` is called. For more information on the `thd`, see Section 16.16.3, “Implementing ROLLBACK”.

7. The savepoint offset. To store per-savepoint data the storage engine is provided with an area of a requested size (`0`, if no savepoint memory is necessary).

   The savepoint offset must be initialized statically to the size of the needed memory to store per-savepoint information. After `foo_init` it is changed to be an offset to the savepoint storage area and need not be used by the storage engine.

   For more information, see Section 16.16.5.1, “Specifying the Savepoint Offset”.

8. Used by transactional storage engines, clean up any memory allocated in their slot.

9. A function pointer to the handler's `savepoint_set()` function. This is used to create a savepoint and store it in memory of the requested size.

   For more information, see Section 16.16.5.2, “Implementing the `savepoint_set` Function”.

10. A function pointer to the handler's `rollback_to_savepoint()` function. This is used to return to a savepoint during a transaction. It's only populated for storage engines that support savepoints.

    For more information, see Section 16.16.5.3, “Implementing the `savepoint_rollback()` Function”.

11. A function pointer to the handler's `release_savepoint()` function. This is used to release the resources of a savepoint during a transaction. It's optionally populated for storage engines that support savepoints.

    For more information, see Section 16.16.5.4, “Implementing the `savepoint_release()` Function”.

12. A function pointer to the handler's `commit()` function. This is used to commit a transaction. It's only populated for storage engines that support transactions.

    For more information, see Section 16.16.4, “Implementing COMMIT”.

13. A function pointer to the handler's `rollback()` function. This is used to roll back a transaction. It's only populated for storage engines that support transactions.

    For more information, see Section 16.16.3, “Implementing ROLLBACK”.

14. Required for XA transactional storage engines. Prepare transaction for commit.

15. Required for XA transactional storage engines. Returns a list of transactions that are in the prepared state.

16. Required for XA transactional storage engines. Commit transaction identified by XID.

17. Required for XA transactional storage engines. Rollback transaction identified by XID.

18. Called when a cursor is created to allow the storage engine to create a consistent read view.

19. Called to switch to a specific consistent read view.

20. Called to close a specific read view.

21. *MANDATORY* - Construct and return a handler instance.

    For more information, see Section 16.5, “Handling Handler Instantiation”.

22. Used if the storage engine needs to perform special steps when a schema is dropped (such as in a storage engine that uses tablespaces).

23. Cleanup function called during server shutdown and crashes.

24. `InnoDB`-specific function.

25. `InnoDB`-specific function called at start of `SHOW ENGINE InnoDB STATUS`.

26. Function called to begin a consistent read.

27. Called to indicate that logs should be flushed to reliable storage.

28. Provides human readable status information on the storage engine for `SHOW ENGINE` *`foo`* `STATUS`.

29. `InnoDB`-specific function used for replication.

30. Handlerton flags that indicate the capabilities of the storage engine. Possible values are defined in `sql/handler.h` and copied here:

    ```
    #define HTON_NO_FLAGS                  0
    #define HTON_CLOSE_CURSORS_AT_COMMIT (1 << 0)
    #define HTON_ALTER_NOT_SUPPORTED     (1 << 1)
    #define HTON_CAN_RECREATE            (1 << 2)
    #define HTON_FLUSH_AFTER_RENAME      (1 << 3)
    #define HTON_NOT_USER_SELECTABLE     (1 << 4)
    ```

    `HTON_ALTER_NOT_SUPPORTED` is used to indicate that the storage engine cannot accept `ALTER TABLE` statements. The `FEDERATED` storage engine is an example.

    `HTON_FLUSH_AFTER_RENAME` indicates that `FLUSH LOGS` must be called after a table rename.

    `HTON_NOT_USER_SELECTABLE` indicates that the storage engine should not be shown when a user calls `SHOW STORAGE ENGINES`. Used for system storage engines such as the dummy storage engine for binary logs.

16.5. Handling Handler Instantiation

The first method call your storage engine needs to support is the call for a new handler instance.

Before the `handlerton` is defined in the storage engine source file, a function header for the instantiation function must be defined. Here is an example from the `CSV` engine:

```
static handler* tina_create_handler(TABLE *table);
```

As you can see, the function accepts a pointer to the table the handler is intended to manage, and returns a handler object.

After the function header is defined, the function is named with a function pointer in the `create()` `handlerton` element, identifying the function as being responsible for generating new handler instances.

Here is an example of the `MyISAM` storage engine's instantiation function:

```
static handler *myisam_create_handler(TABLE *table)
```

```
  {
    return new ha_myisam(table);
  }
```

This call then works in conjunction with the storage engine's constructor. Here is an example from the FEDERATED storage engine:

```
ha_federated::ha_federated(TABLE *table_arg)
  :handler(&federated_hton, table_arg),
  mysql(0), stored_result(0), scan_flag(0),
  ref_length(sizeof(MYSQL_ROW_OFFSET)), current_position(0)
  {}
```

And here's one more example from the EXAMPLE storage engine:

```
ha_example::ha_example(TABLE *table_arg)
  :handler(&example_hton, table_arg)
  {}
```

The additional elements in the FEDERATED example are extra initializations for the handler. The minimum implementation required is the handler() initialization shown in the EXAMPLE version.

16.6. Defining Filename Extensions

Storage engines are required to provide the MySQL server with a list of extensions used by the storage engine with regards to a given table, its data and indexes.

Extensions are expected in the form of a null-terminated string array. The following is the array used by the CSV engine:

```
static const char *ha_tina_exts[] = {
  ".CSV",
  NullS
};
```

This array is returned when the bas_ext() function is called:

```
const char **ha_tina::bas_ext() const
{
  return ha_tina_exts;
}
```

By providing extension information you can also omit implementing DROP TABLE functionality as the MySQL server will implement it for you by closing the table and deleting all files with the extensions you specify.

16.7. Creating Tables

Once a handler is instanced, the first operation that will likely be required is the creation of a table.

Your storage engine must implement the create() virtual function:

```
virtual int create(const char *name, TABLE *form, HA_CREATE_INFO *info)=0;
```

This function should create all necessary files but does not need to open the table. The MySQL server will call for the table to be opened later on.

The *name parameter is the name of the table. The *form parameter is a TABLE structure that defines the table and matches the contents of the *tablename*.frm file already created by the MySQL server. Storage engines must not modify the *tablename*.frm file.

The *info parameter is a structure containing information on the CREATE TABLE statement used to create the table. The structure is defined in handler.h and copied here for your convenience:

```
typedef struct st_ha_create_information
{
    CHARSET_INFO *table_charset, *default_table_charset;
    LEX_STRING connect_string;
    const char *comment,*password;
    const char *data_file_name, *index_file_name;
    const char *alias;
    ulonglong max_rows,min_rows;
    ulonglong auto_increment_value;
    ulong table_options;
    ulong avg_row_length;
    ulong raid_chunksize;
    ulong used_fields;
    SQL_LIST merge_list;
    enum db_type db_type;
    enum row_type row_type;
    uint null_bits;                       /* NULL bits at start of record */
    uint options;                         /* OR of HA_CREATE_ options */
    uint raid_type,raid_chunks;
    uint merge_insert_method;
    uint extra_size;                      /* length of extra data segment */
    bool table_existed;                 /* 1 in create if table existed */
    bool frm_only;                        /* 1 if no ha_create_table() */
    bool varchar;                         /* 1 if table has a VARCHAR */
} HA_CREATE_INFO;
```

A basic storage engine can ignore the contents of *form and *info, as all that is really required is the creation and possibly the initialization of the data files used by the storage engine (assuming the storage engine is file-based).

For example, here is the implementation from the CSV storage engine:

```
int ha_tina::create(const char *name, TABLE *table_arg,
  HA_CREATE_INFO *create_info)
{
    char name_buff[FN_REFLEN];
    File create_file;
    DBUG_ENTER("ha_tina::create");

    if ((create_file= my_create(fn_format(name_buff, name, "", ".CSV",
          MY_REPLACE_EXT|MY_UNPACK_FILENAME),0,
          O_RDWR | O_TRUNC,MYF(MY_WME))) < 0)
    DBUG_RETURN(-1);

    my_close(create_file,MYF(0));

    DBUG_RETURN(0);
}
```

In the preceding example, the CSV engine does not refer at all to the *table_arg or *create_info parameters, but simply creates the required data files, closes them, and returns.

The my_create and my_close functions are helper functions defined in src/include/my_sys.h.

16.8. Opening a Table

Before any read or write operations are performed on a table, the MySQL server will call the handler::open() method to open the table data and index files (if they exist).

```
int open(const char *name, int mode, int test_if_locked);
```

The first parameter is the name of the table to be opened. The second parameter determines what file to open or what operation to take. The values are defined in `handler.h` and are copied here for your convenience:

```
O_RDONLY  -  Open read only
O_RDWR    -  Open read/write
```

The final option dictates whether the handler should check for a lock on the table before opening it. The following options are available:

```
#define HA_OPEN_ABORT_IF_LOCKED   0   /* default */
#define HA_OPEN_WAIT_IF_LOCKED    1
#define HA_OPEN_IGNORE_IF_LOCKED  2
#define HA_OPEN_TMP_TABLE         4   /* Table is a temp table */
#define HA_OPEN_DELAY_KEY_WRITE   8   /* Don't update index */
#define HA_OPEN_ABORT_IF_CRASHED  16
#define HA_OPEN_FOR_REPAIR        32  /* open even if crashed */
```

Typically your storage engine will need to implement some form of shared access control to prevent file corruption is a multi-threaded environment. For an example of how to implement file locking, see the `get_share()` and `free_share()` methods of `sql/examples/ha_tina.cc`.

16.9. Implementing Basic Table Scanning

The most basic storage engines implement read-only table scanning. Such engines might be used to support SQL queries of logs and other data files that are populated outside of MySQL.

The implementation of the methods in this section provide the first steps toward the creation of more advanced storage engines.

The following shows the method calls made during a nine-row table scan of the `CSV` engine:

```
ha_tina::store_lock
ha_tina::external_lock
ha_tina::info
ha_tina::rnd_init
ha_tina::extra - ENUM HA_EXTRA_CACHE   Cache record in HA_rrnd()
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::rnd_next
ha_tina::extra - ENUM HA_EXTRA_NO_CACHE   End caching of records (def)
ha_tina::external_lock
ha_tina::extra - ENUM HA_EXTRA_RESET   Reset database to after open
```

16.9.1. Implementing the `store_lock()` Function

The `store_lock()` function is called before any reading or writing is performed.

Before adding the lock into the table lock handler `mysqld` calls store lock with the requested locks.

Store lock can modify the lock level, for example change blocking write lock to non-blocking, ignore the lock (if we don't want to use MySQL table locks at all) or add locks for many tables (like we do when we are using a MERGE handler).

Berkeley DB, for example, downgrades blocking table `TL_WRITE` locks to non-blocking `TL_WRITE_ALLOW_WRITE` locks (which signals that we are doing `WRITE`s, but we are still allowing other readers and writers).

When releasing locks, `store_lock()` are also called. In this case one usually doesn't have to do anything.

If the argument of `store_lock` is `TL_IGNORE`, it means that MySQL requests the handler to store the same lock level as the last time.

The potential lock types are defined in `includes/thr_lock.h` and are copied here:

```
enum thr_lock_type
{
        TL_IGNORE=-1,
        TL_UNLOCK,                              /* UNLOCK ANY LOCK */
          TL_READ,                                /* Read lock */
          TL_READ_WITH_SHARED_LOCKS,
        TL_READ_HIGH_PRIORITY,      /* High prior. than TL_WRITE. Allow concur
        TL_READ_NO_INSERT,                      /* READ, Don't allow concurren
        TL_WRITE_ALLOW_WRITE,                    /* Write lock, but allow othe
        TL_WRITE_ALLOW_READ,        /* Write lock, but allow other threads to
        TL_WRITE_CONCURRENT_INSERT, /* WRITE lock used by concurrent insert. *
        TL_WRITE_DELAYED,                       /* Write used by INSERT DELAYE
        TL_WRITE_LOW_PRIORITY,      /* WRITE lock that has lower priority than
        TL_WRITE,                               /* Normal WRITE lock */
        TL_WRITE_ONLY               /* Abort new lock request with an error */
};
```

Actual lock handling will vary depending on your locking implementation and you may choose to implement some or none of the requested lock types, substituting your own methods as appropriate. The following is the minimal implementation, for a storage engine that does not need to downgrade locks:

```
THR_LOCK_DATA **ha_tina::store_lock(THD *thd,
                                   THR_LOCK_DATA **to,
                                   enum thr_lock_type lock_type)
{
   if (lock_type != TL_IGNORE && lock.type == TL_UNLOCK)
     lock.type=lock_type;
   *to++= &lock;
   return to;
}
```

See also `ha_berkeley::store_lock()` and `ha_myisammrg::store_lock()` for a more complex implementation.

16.9.2. Implementing the `external_lock()` Function

The `external_lock()` function is called at the start of a statement or when a `LOCK TABLES` statement is issued.

Examples of using `external_lock()` can be found in the `sql/ha_innodb.cc` and `sql/ha_berkeley.cc` files, but most storage engines can simply return `0`, as is the case with the `EXAMPLE` storage engine:

```
int ha_example::external_lock(THD *thd, int lock_type)
{
   DBUG_ENTER("ha_example::external_lock");
   DBUG_RETURN(0);
```

```
}
```

16.9.3. Implementing the `rnd_init()` Function

The function called before any table scan is the `rnd_init()` function. The `rnd_init()` function is used to prepare for a table scan, resetting counters and pointers to the start of the table.

The following example is from the CSV storage engine:

```
  int ha_tina::rnd_init(bool scan)
{
      DBUG_ENTER("ha_tina::rnd_init");

      current_position= next_position= 0;
      records= 0;
      chain_ptr= chain;

      DBUG_RETURN(0);
}
```

If the `scan` parameter is true, the MySQL server will perform a sequential table scan, if false the MySQL server will perform random reads by position.

16.9.4. Implementing the `info()` Function

Prior to commencing a table scan, the `info()` function is called to provide extra table information to the optimizer.

The information required by the optimizer is not given through return values but instead by populating certain properties of the storage engine class, which the optimizer reads after the `info()` call returns.

In addition to being used by the optimizer, many of the values set during a call to the `info()` function are also used for the `SHOW TABLE STATUS` statement.

The public properties are listed in full in `sql/handler.h`; several of the more common ones are copied here:

```
ulonglong data_file_length;         /* Length off data file */
ulonglong max_data_file_length; /* Length off data file */
ulonglong index_file_length;
ulonglong max_index_file_length;
ulonglong delete_length;          /* Free bytes */
ulonglong auto_increment_value;
ha_rows records;                  /* Records in table */
ha_rows deleted;                  /* Deleted records */
ulong raid_chunksize;
ulong mean_rec_length;          /* physical reclength */
time_t create_time;                  /* When table was created */
time_t check_time;
time_t update_time;
```

For the purposes of a table scan, the most important property is `records`, which indicates the number of records in the table. The optimizer will perform differently when the storage engine indicates that there are zero or one rows in the table than it will when there are two or more. For this reason it is important to return a value of two or greater when you do not actually know how many rows are in the table before you perform the table scan (such as in a situation where the data may be externally populated).

16.9.5. Implementing the `extra()` Function

Prior to some operations, the `extra()` function is called to provide extra hints to the storage engine on how to perform certain operations.

Implementation of the hints in the `extra` call is not mandatory, and most storage engines return `0`:

```
int ha_tina::extra(enum ha_extra_function operation)
{
   DBUG_ENTER("ha_tina::extra");
   DBUG_RETURN(0);
}
```

16.9.6. Implementing the `rnd_next()` Function

After the table is initialized, the MySQL server will call the handler's `rnd_next()` function once for every row to be scanned until the server's search condition is satisfied or an end of file is reached, in which case the handler returns `HA_ERR_END_OF_FILE`.

The `rnd_next()` function takes a single byte array parameter named `*buf`. The `*buf` parameter must be populated with the contents of the table row in the internal MySQL format.

The server uses three data formats: fixed-length rows, variable-length rows, and variable-length rows with BLOB pointers. In each format, the columns appear in the order in which they were defined by the CREATE TABLE statement. (The table definition is stored in the `.frm` file, and the optimizer and the handler are both able to access table metadata from the same source, its `TABLE` structure).

Each format begins with a “NULL bitmap” of one bit per nullable column. A table with as many as eight nullable columns will have a one-byte bitmap; a table with nine to sixteen nullable columns will have a two-byte bitmap, and so forth. One exception is fixed-width tables, which have an additional starting bit so that a table with eight nullable columns would have a two-byte bitmap.

After the NULL bitmap come the columns, one by one. Each column is of the size indicated in Chapter 11, *Data Types*. In the server, column data types are defined in the `sql/field.cc` file. In the fixed length row format, the columns are simply laid out one by one. In a variable-length row, `VARCHAR` columns are coded as a one or two-byte length, followed by a string of characters. In a variable-length row with `BLOB` columns, each blob is represented by two parts: first an integer representing the actual size of the `BLOB`, and then a pointer to the `BLOB` in memory.

Examples of row conversion (or “packing”) can be found by starting at `rnd_next()` in any table handler. In `ha_tina.cc`, for example, the code in `find_current_row()` illustrates how the `TABLE` structure (pointed to by table) and a string object (named buffer) can be used to pack character data from a CSV file. Writing a row back to disk requires the opposite conversion, unpacking from the internal format.

The following example is from the `CSV` storage engine:

```
int ha_tina::rnd_next(byte *buf)
{
   DBUG_ENTER("ha_tina::rnd_next");

   statistic_increment(table->in_use->status_var.ha_read_rnd_next_count, &LOCK_

   current_position= next_position;
   if (!share->mapped_file)
     DBUG_RETURN(HA_ERR_END_OF_FILE);
   if (HA_ERR_END_OF_FILE == find_current_row(buf) )
     DBUG_RETURN(HA_ERR_END_OF_FILE);

   records++;
   DBUG_RETURN(0);
}
```

The conversion from the internal row format to CSV row format is performed in the

`find_current_row()` function:

```
int ha_tina::find_current_row(byte *buf)
{
   byte *mapped_ptr= (byte *)share->mapped_file + current_position;
   byte *end_ptr;
   DBUG_ENTER("ha_tina::find_current_row");

   /* EOF should be counted as new line */
   if ((end_ptr=  find_eoln(share->mapped_file, current_position,
                            share->file_stat.st_size)) == 0)
     DBUG_RETURN(HA_ERR_END_OF_FILE);

   for (Field **field=table->field ; *field ; field++)
   {
     buffer.length(0);
     mapped_ptr++; // Increment past the first quote
     for(;mapped_ptr != end_ptr; mapped_ptr++)
     {
       // Need to convert line feeds!
       if (*mapped_ptr == '"' &&
           (((mapped_ptr[1] == ',') && (mapped_ptr[2] == '")) ||
            (mapped_ptr == end_ptr -1 )))
       {
         mapped_ptr += 2; // Move past the , and the "
         break;
       }
       if (*mapped_ptr == '\\' && mapped_ptr != (end_ptr - 1))
       {
         mapped_ptr++;
         if (*mapped_ptr == 'r')
           buffer.append('\r');
         else if (*mapped_ptr == 'n' )
           buffer.append('\n');
         else if ((*mapped_ptr == '\\') || (*mapped_ptr == '"'))
           buffer.append(*mapped_ptr);
         else  /* This could only happed with an externally created file */
         {
           buffer.append('\\');
           buffer.append(*mapped_ptr);
         }
       }
       else
         buffer.append(*mapped_ptr);
     }
     (*field)->store(buffer.ptr(), buffer.length(), system_charset_info);
   }
   next_position= (end_ptr - share->mapped_file)+1;
   /* Maybe use \N for null? */
   memset(buf, 0, table->s->null_bytes); /* We do not implement nulls! */

   DBUG_RETURN(0);
}
```

16.10. Closing a Table

When the MySQL server is finished with a table, it will call the close() method to close file pointers and release any other resources.

Storage engines that use the shared access methods seen in the `CSV` engine and other example engines must remove themselves from the shared structure:

```
int ha_tina::close(void)
 {
   DBUG_ENTER("ha_tina::close");
   DBUG_RETURN(free_share(share));
 }
```

Storage engines using their own share management systems should use whatever methods are needed to remove the handler instance from the share for the table opened in their handler.

16.11. Adding Support for INSERT to a Storage Engine

Once you have read support in your storage engine, the next feature to implement is support for INSERT statements. With INSERT support in place, your storage engine can handle WORM (write once, read many) applications such as logging and archiving for later analysis.

All INSERT operations are handled through the write_row() function:

```
int ha_foo::write_row(byte *buf)
```

The *buf parameter contains the row to be inserted in the internal MySQL format. A basic storage engine could simply advance to the end of the data file and append the contents of the buffer directly (this would also make reading rows easier as you could read the row and pass it directly into the buffer parameter of the rnd_next() function.

The process for writing a row is the opposite of the process for reading one: take the data from the MySQL internal row format and write it to the data file. The following example is from the MyISAM storage engine:

```
int ha_myisam::write_row(byte * buf)
{
  statistic_increment(table->in_use->status_var.ha_write_count,&LOCK_status);

  /* If we have a timestamp column, update it to the current time */
  if (table->timestamp_field_type & TIMESTAMP_AUTO_SET_ON_INSERT)
    table->timestamp_field->set_time();

  /*
    If we have an auto_increment column and we are writing a changed row
    or a new row, then update the auto_increment value in the record.
  */
  if (table->next_number_field && buf == table->record[0])
    update_auto_increment();
  return mi_write(file,buf);
}
```

Three items of note in the preceding example include the updating of table statistics for writes, the setting of the timestamp prior to writing the row, and the updating of AUTO_INCREMENT values.

16.12. Adding Support for UPDATE to a Storage Engine

The MySQL server executes UPDATE statements by performing a (table/index/range/etc.) scan until it locates a row matching the WHERE clause of the UPDATE statement, then calling the update_row() function:

```
int ha_foo::update_row(const byte *old_data, byte *new_data)
```

The *old_data parameter contains the data that existed in the row prior to the update, while the *new_data parameter contains the new contents of the row (in the MySQL internal row format).

Performing an update will depend on row format and storage implementation. Some storage engines

will replace data in-place, while other implementations delete the existing row and append the new row at the end of the data file.

Non-indexed storage engines can typically ignore the contents of the `*old_data` parameter and just deal with the `*new_data` buffer. Transactional engines may need to compare the buffers to determine what changes have been made for a later rollback.

If the table being updated contains timestamp columns, the updating of the timestamp will have to be managed in the `update_row()` call. The following example is from the `CSV` engine:

```
int ha_tina::update_row(const byte * old_data, byte * new_data)
{
   int size;
   DBUG_ENTER("ha_tina::update_row");

   statistic_increment(table->in_use->status_var.ha_read_rnd_next_count,
                       &LOCK_status);

   if (table->timestamp_field_type & TIMESTAMP_AUTO_SET_ON_UPDATE)
     table->timestamp_field->set_time();

   size= encode_quote(new_data);

   if (chain_append())
     DBUG_RETURN(-1);

   if (my_write(share->data_file, buffer.ptr(), size, MYF(MY_WME | MY_NABP)))
     DBUG_RETURN(-1);
   DBUG_RETURN(0);
}
```

Note the setting of the timestamp in the previous example.

16.13. Adding Support for `DELETE` to a Storage Engine

The MySQL server executes `DELETE` statements using the same approach as for `UPDATE` statements: It advances to the row to be deleted using the `rnd_next()` function and then calls the `delete_row()` function to delete the row:

```
int ha_foo::delete_row(const byte *buf)
```

The `*buf` parameter contains the contents of the row to be deleted. For non-indexed storage engines the parameter can be ignored, but transactional storage engines may need to store the deleted data for rollback purposes.

The following example is from the `CSV` storage engine:

```
int ha_tina::delete_row(const byte * buf)
{
   DBUG_ENTER("ha_tina::delete_row");
   statistic_increment(table->in_use->status_var.ha_delete_count,
                       &LOCK_status);

   if (chain_append())
     DBUG_RETURN(-1);

   --records;

   DBUG_RETURN(0);
}
```

The steps of note in the preceding example are the update of the `delete_count` statistic and the record count.

16.14. Supporting Non-Sequential Reads

In addition to table scanning, storage engines can implement functions for non-sequential reading. The MySQL server uses these functions for certain sort operations.

16.14.1. Implementing the `position()` Function

The `position()` function is called after every call to `rnd_next()` if the data needs to be re-ordered:

```
void ha_foo::position(const byte *record)
```

The contents of `*record` are up to you — whatever value you provide will be returned in a later call to retrieve the row. Most storage engines will store some form of offset or primary key value.

16.14.2. Implementing the `rnd_pos()` Function

The `rnd_pos()` function behaves in a similar fashion to the `rnd_next()` function but takes an additional parameter:

```
int ha_foo::rnd_pos(byte * buf, byte *pos)
```

The `*pos` parameter contains positioning information previously recorded using the `position()` function.

A storage engine must locate the row specified by the position and return it through `*buf` in the internal MySQL row format.

16.15. Supporting Indexing

Once basic read/write operations are implemented in a storage engine, the next stage is to add support for indexing. Without indexing, a storage engine's performance is quite limited.

This section documents the methods that must be implemented to add support for indexing to a storage engine.

16.15.1. Indexing Overview

Adding index support to a storage engine revolves around two tasks: providing information to the optimizer and implementing index-related methods. The information provided to the optimizer helps the optimizer to make better decisions about which index to use or even to skip using an index and instead perform a table scan.

The indexing methods either read rows that match a key, scan a set of rows by index order, or read information directly from the index.

The following example shows the function calls made during an `UPDATE` query that uses an index, such as `UPDATE foo SET ts = now() WHERE id = 1`:

```
ha_foo::index_init
ha_foo::index_read
ha_foo::index_read_idx
ha_foo::rnd_next
ha_foo::update_row
```

In addition to index reading methods, your storage engine must support the creation of new indexes and be able to keep table indexes up to date as rows are added, modified, and removed from tables.

16.15.2. Getting Index Information During CREATE TABLE Operations

It is preferable for storage engines that support indexing to read the index information provided during a `CREATE TABLE` operation and store it for future use. The reasoning behind this is that the index information is most readily available during table and index creation and is not as easily retrieved afterwards.

The table index information is contained within the `key_info` structure of the `TABLE` argument of the `create()` function.

Within the `key_info` structure there is a `flag` that defines index behavior:

```
#define HA_NOSAME             1  /* Set if not duplicated records   */
#define HA_PACK_KEY           2  /* Pack string key to previous key */
#define HA_AUTO_KEY          16
#define HA_BINARY_PACK_KEY   32 /* Packing of all keys to prev key */
#define HA_FULLTEXT         128 /* For full-text search            */
#define HA_UNIQUE_CHECK     256 /* Check the key for uniqueness    */
#define HA_SPATIAL         1024 /* For spatial search              */
#define HA_NULL_ARE_EQUAL  2048 /* NULL in key are cmp as equal    */
#define HA_GENERATED_KEY   8192 /* Automatically generated key     */
```

In addition to the `flag`, there is an enumerator named `algorithm` that specifies the desired index type:

```
enum ha_key_alg {
  HA_KEY_ALG_UNDEF=     0,  /* Not specified (old file)     */
  HA_KEY_ALG_BTREE=     1,  /* B-tree, default one          */
  HA_KEY_ALG_RTREE=     2,  /* R-tree, for spatial searches */
  HA_KEY_ALG_HASH=      3,  /* HASH keys (HEAP tables)      */
  HA_KEY_ALG_FULLTEXT=  4   /* FULLTEXT (MyISAM tables)     */
};
```

In addition to the `flag` and `algorithm`, there is an array of `key_part` elements that describe the individual parts of a composite key.

The key parts define the field associated with the key part, whether the key should be packed, and the data type and length of the index part. See `ha_myisam.cc` for an example of how this information is parsed.

As an alternative, a storage engine can instead follow the example of `ha_berkeley.cc` and read index information from the `TABLE` structure of the handler during each operation.

16.15.3. Creating Index Keys

As part of every table-write operation (`INSERT`, `UPDATE`, `DELETE`), the storage engine is required to update its internal index information.

The method used to update indexes will vary from storage engine to storage engine, depending on the method used to store the index.

In general, the storage engine will have to use row information passed in functions such as `write_row()`, `delete_row()`, and `update_row()` in combination with index information for the table to determine what index data needs to be modified, and make the needed changes.

The method of associating an index with its row will depend on your storage approach. The `BerkeleyDB` storage engine stores the primary key of the row in the index while other storage en-

gines often store the row offset.

16.15.4. Parsing Key Information

Many of the index methods pass a byte array named `*key` that identifies the index entry to be read in a standard format. Your storage engine will need to extract the information stored in the key and translate it into its internal index format in order to identify the row associated with the index.

The information in the key is obtained by iterating through the key, which is formatted the same as the definition in `table->key_info[`*`index`*`]->key_part[`*`part_num`*`]`. The following example from `ha_berkeley.cc` shows how the `BerkeleyDB` storage engine takes a key defined in `*key` and converts it to internal key format:

```
/*
Create a packed key from a MySQL unpacked key (like the one that is
sent from the index_read()

This key is to be used to read a row
*/

DBT *ha_berkeley::pack_key(DBT *key, uint keynr, char *buff,
                                                 const byte *key_ptr, uint key_l
{
  KEY *key_info=table->key_info+keynr;
  KEY_PART_INFO *key_part=key_info->key_part;
  KEY_PART_INFO *end=key_part+key_info->key_parts;
  DBUG_ENTER("bdb:pack_key");

  bzero((char*) key,sizeof(*key));
  key->data=buff;
  key->app_private= (void*) key_info;

  for (; key_part != end && (int) key_length > 0 ; key_part++)
  {
      uint offset=0;
      if (key_part->null_bit)
      {
          if (!(*buff++ = (*key_ptr == 0)))         // Store 0 if NULL
          {
              key_length-= key_part->store_length;
              key_ptr+=   key_part->store_length;
              key->flags|=DB_DBT_DUPOK;
              continue;
          }
          offset=1;                                 // Data is at key_ptr+1
      }
      buff=key_part->field->pack_key_from_key_image(buff,(char*) key_ptr+offset
      key_part->length);
      key_ptr+=key_part->store_length;
      key_length-=key_part->store_length;
  }
  key->size= (buff  - (char*) key->data);
  DBUG_DUMP("key",(char*) key->data, key->size);
  DBUG_RETURN(key);
}
```

16.15.5. Providing Index Information to the Optimizer

In order for indexing to be used effectively, storage engines need to provide the optimizer with information about the table and its indexes. This information is used to choose whether to use an index, and if so, which index to use.

16.15.5.1. Implementing the `info()` Function

The optimizer requests an update of table information by calling the `handler::info()` function.

The `info()` function does not have a return value, instead it is expected that the storage engine will set a variety of public variables that the server will then read as needed. These values are also used to populate certain `SHOW` outputs such as `SHOW TABLE STATUS` and for queries of the `INFORMATION_SCHEMA`.

All variables are optional but should be filled if possible:

- `records` - The number of rows in the table. If you cannot provide an accurate number quickly you should set the value to be greater than 1 so that the optimizer does not perform optimizations for zero or one row tables.
- `deleted` - Number of deleted rows in table. Used to identify table fragmentation, where applicable.
- `data_file_length` - Size of the data file, in bytes. Helps optimizer calculate the cost of reads.
- `index_file_length` - Size of the index file, in bytes. Helps optimizer calculate the cost of reads.
- `mean_rec_length` - Average length of a single row, in bytes.
- `scan_time` - Cost in I/O seeks to perform a full table scan.
- `delete_length` -
- `check_time` -

When calculating values, speed is more important than accuracy, as there is no sense in taking a long time to give the optimizer clues as to what approach may be the fastest. Estimates within an order of magnitude are usually good enough.

16.15.5.2. Implementing the `records_in_range` Function

The `records_in_range()` function is called by the optimizer to assist in choosing which index on a table to use for a query or join. It is defined as follows:

```
ha_rows ha_foo::records_in_range(uint inx, key_range *min_key, key_range *max_k
```

The `inx` parameter is the index to be checked. The `*min_key` parameter is the low end of the range while the `*max_key` parameter is the high end of the range.

`min_key.flag` can have one of the following values:

- `HA_READ_KEY_EXACT` - Include the key in the range
- `HA_READ_AFTER_KEY` - Don't include key in range

`max_key.flag` can have one of the following values:

- `HA_READ_BEFORE_KEY` - Don't include key in range
- `HA_READ_AFTER_KEY` - Include all 'end_key' values in the range

The following return values are allowed:

- `0` - There are no matching keys in the given range

- `number > 0` - There is approximately *`number`* matching rows in the range
- `HA_POS_ERROR` - Something is wrong with the index tree

When calculating values, speed is more important than accuracy.

16.15.6. Preparing for Index Use with `index_init()`

The `index_init()` function is called before an index is used to allow the storage engine to perform any necessary preparation or optimization:

```
int ha_foo::index_init(uint keynr, bool sorted)
```

Most storage engines do not need to make special preparations, in which case a default implementation will be used if the method is not explicitly implemented in the storage engine:

```
int handler::index_init(uint idx) { active_index=idx; return 0; }
```

16.15.7. Cleaning up with `index_end()`

The `index_end()` function is a counterpart to the `index_init()` function. The purpose of the `index_end()` function is to clean up any preparations made by the `index_init()` function.

If a storage engine does not implement `index_init()` it does not need to implement `index_end()`.

16.15.8. Implementing the `index_read()` Function

The `index_read()` function is used to retrieve a row based on a key:

```
int ha_foo::index_read(byte * buf, const byte * key, uint key_len, enum ha_rkey
```

The `*buf` parameter is a byte array that the storage engine populates with the row that matches the index key specified in `*key`. The `key_len` parameter indicates the prefix length when matching by prefix, and the `find_flag` parameter is an enumerator that dictates the search behavior to be used.

The index to be used is previously defined in the `index_init()` call and is stored in the `active_index` handler variable.

The following values are allowed for `find_flag`:

```
HA_READ_KEY_EXACT
HA_READ_KEY_OR_NEXT
HA_READ_PREFIX_LAST
HA_READ_PREFIX_LAST_OR_PREV
HA_READ_BEFORE_KEY
HA_READ_AFTER_KEY
HA_READ_KEY_OR_NEXT
HA_READ_KEY_OR_PREV
```

Storage engines must convert the `*key` parameter to a storage engine-specific format, use it to find the matching row according to the `find_flag`, and then populate `*buf` with the matching row in the MySQL internal row format. For more information on the internal row format, see Section 16.9.6, “Implementing the `rnd_next()` Function”.

In addition to returning a matching row, the storage engine must also set a cursor to support sequential index reads.

If the `*key` parameter is null the storage engine should read the first key in the index.

16.15.9. Implementing the `index_read_idx()` Function

The `index_read_idx()` function is identical to the `index_read()` with the exception that `index_read_idx()` accepts an additional `keynr` parameter:

```
int ha_foo::index_read_idx(byte * buf, uint keynr, const byte * key,
                           uint key_len, enum ha_rkey_function find_flag)
```

The `keynr` parameter specifies the index to be read, as opposed to `index_read` where the index is already set.

As with the `index_read()` function, the storage engine must return the row that matches the key according to the `find_flag` and set a cursor for future reads.

16.15.10. Implementing the `index_next()` Function

The `index_next()` function is used for index scanning:

```
int ha_foo::index_next(byte * buf)
```

The `*buf` parameter is populated with the row that corresponds to the next matching key value according to the internal cursor set by the storage engine during operations such as `index_read()` and `index_first()`.

16.15.11. Implementing the `index_prev()` Function

The `index_prev()` function is used for reverse index scanning:

```
        int ha_foo::index_prev(byte * buf)
```

The `*buf` parameter is populated with the row that corresponds to the previous matching key value according to the internal cursor set by the storage engine during operations such as `index_read()` and `index_last()`.

16.15.12. Implementing the `index_first()` Function

The `index_first()` function is used for index scanning:

```
        int ha_foo::index_first(byte * buf)
```

The `*buf` parameter is populated with the row that corresponds to the first key value in the index.

16.15.13. Implementing the `index_last()` Function

The `index_last()` function is used for reverse index scanning:

```
        int ha_foo::index_last(byte * buf)
```

The `*buf` parameter is populated with the row that corresponds to the last key value in the index.

16.16. Supporting Transactions

This section documents the methods that must be implemented to add support for transactions to a storage engine.

Please note that transaction management can be complicated and involve methods such as row versioning and redo logs, which is beyond the scope of this document. Instead coverage is limited to a description of required methods and not their implementation. For examples of implementation, please see `ha_innodb.cc` and `ha_berkeley.cc`.

16.16.1. Transaction Overview

Transactions are not explicitly started on the storage engine level, but are instead implicitly started through calls to either `start_stmt()` or `external_lock()`. If the preceding functions are called and a transaction already exists the transaction is not replaced.

The storage engine stores transaction information in per-connection memory and also registers the transaction in the MySQL server to allow the server to later issue `COMMIT` and `ROLLBACK` operations.

As operations are performed the storage engine will have to implement some form of versioning or logging to permit a rollback of all operations executed within the transaction.

After work is completed, the MySQL server will call either the `commit()` function or the `rollback()` function defined in the storage engine's handlerton.

16.16.2. Starting a Transaction

A transaction is started by the storage engine in response to a call to either the `start_stmt()` or `external_lock()` functions.

If there is no active transaction, the storage engine must start a new transaction and register the transaction with the MySQL server so that `ROLLBACK` or `COMMIT` can later be called.

16.16.2.1. Starting a Transaction from a `start_stmt()` Call

The first function call that can start a transaction is the `start_stmt()` function.

The following example shows how a storage engine could register a transaction:

```
int my_handler::start_stmt(THD *thd, thr_lock_type lock_type)
{
  int error= 0;
  my_txn *txn= (my_txn *) thd->ha_data[my_handler_hton.slot];

  if (txn == NULL)
  {
    thd->ha_data[my_handler_hton.slot]= txn= new my_txn;
  }
  if (txn->stmt == NULL && !(error= txn->tx_begin()))
  {
    txn->stmt= txn->new_savepoint();
    trans_register_ha(thd, FALSE, &my_handler_hton);
  }
  return error;
}
```

`THD` is the current client connection. It holds state relevant data for the current client, such as identity, network connection and other per-connection data.

`thd->ha_data[my_handler_hton.slot]` is a pointer in `thd` to the connection-specific data of this storage engine. In this example we use it to store the transaction context.

An additional example of implementing `start_stmt()` can be found in `ha_innodb.cc`.

16.16.2.2. Starting a Transaction from a `external_lock()` Function

MySQL calls `handler::external_lock()` for every table it is going to use at the beginning of every statement. Thus, if a table is touched for the first time, it implicitly starts a transaction.

Note that because of pre-locking, all tables that can be potentially used between the beginning and the end of a statement are locked before the statement execution begins and `handler::external_lock()` is called for all these tables. That is, if an `INSERT` fires a trigger, which calls a stored procedure, that invokes a stored function, and so forth, all tables used in the trigger, stored procedure, function, etc., are locked in the beginning of the `INSERT`. Additionally, if there's a construct like

```
IF
.. use one table
ELSE
.. use another table
```

both tables will be locked.

Also, if a user calls `LOCK TABLES`, MySQL will call `handler::external_lock` only once. In this case, MySQL will call `handler::start_stmt()` at the beginning of the statement.

The following example shows how a storage engine can start a transaction and take locking requests into account:

```
int my_handler::external_lock(THD *thd, int lock_type)
{
  int error= 0;
  my_txn *txn= (my_txn *) thd->ha_data[my_handler_hton.slot];

  if (txn == NULL)
  {
    thd->ha_data[my_handler_hton.slot]= txn= new my_txn;
  }

  if (lock_type != F_UNLCK)
  {
    bool all_tx= 0;
    if (txn->lock_count == 0)
    {
      txn->lock_count= 1;
      txn->tx_isolation= thd->variables.tx_isolation;

      all_tx= test(thd->options & (OPTION_NOT_AUTOCOMMIT | OPTION_BEGIN | OPTIO
    }

    if (all_tx)
    {
      txn->tx_begin();
      trans_register_ha(thd, TRUE, &my_handler_hton);
    }
    else
    if (txn->stmt == 0)
    {
      txn->stmt= txn->new_savepoint();
      trans_register_ha(thd, FALSE, &my_handler_hton);
    }
  }
  else
  {
    if (txn->stmt != NULL)
    {
      /* Commit the transaction if we're in auto-commit mode */
      my_handler_commit(thd, FALSE);
```

```
      delete txn->stmt; // delete savepoint
      txn->stmt= NULL;
    }
  }

  return error;
}
```

Every storage engine must call `trans_register_ha()` every time it starts a transaction. The `trans_register_ha()` function registers a transaction with the MySQL server to allow for future `COMMIT` and `ROLLBACK` calls.

An additional example of implementing `external_lock()` can be found in `ha_innodb.cc`.

16.16.3. Implementing ROLLBACK

Of the two major transactional operations, `ROLLBACK` is the more complicated to implement. All operations that occurred during the transaction must be reversed so that all rows are unchanged from before the transaction began.

To support `ROLLBACK`, create a function that matches this definition:

```
int  (*rollback)(THD *thd, bool all);
```

The function name is then listed in the `rollback` (thirteenth) entry of the handlerton.

The `THD` parameter is used to identify the transaction that needs to be rolled back, while the `bool all` parameter indicates whether the entire transaction should be rolled back or just the last statement.

Details of implementing a `ROLLBACK` operation will vary by storage engine. Examples can be found in `ha_innodb.cc` and `ha_berkeley.cc`.

16.16.4. Implementing COMMIT

During a commit operation, all changes made during a transaction are made permanent and afterwards a rollback operation is not possible. Depending on the transaction isolation used, this may be the first time such changes are visible to other threads.

To support `COMMIT`, create a function that matches this definition:

```
        int  (*commit)(THD *thd, bool all);
```

The function name is then listed in the `rollback` (twelfth) entry of the handlerton.

The `THD` parameter is used to identify the transaction that needs to be committed, while the `bool all` parameter indicates if this is a full transaction commit or just the end of a statement that is part of the transaction.

Details of implementing a `COMMIT` operation will vary by storage engine. Examples can be found in `ha_innodb.cc` and `ha_berkeley.cc`.

If the server is in auto-commit mode, the storage engine should automatically commit all read-only statements such as `SELECT`.

In a storage engine, "auto-committing" works by counting locks. Increment the count for every call to `external_lock()`, decrement when `external_lock()` is called with an argument of `F_UNLCK`. When the count drops to zero, trigger a commit.

16.16.5. Adding Support for Savepoints

First, the implementor should know how many bytes are required to store savepoint information. This should be a fixed size, preferably not large as the MySQL server will allocate space to store the savepoint for all storage engines with each named savepoint.

The implementor should store the data in the space preallocated by mysqld - and use the contents from the preallocated space for rollback or release savepoint operations.

When a `COMMIT` or `ROLLBACK` operation occurs (with `bool all` set to `true`), all savepoints are assumed to be released. If the storage engine allocates resources for savepoints, it should free them.

The following handlerton elements need to be implemented to support savepoints (elements 7,9,10,11):

```
uint savepoint_offset;
int  (*savepoint_set)(THD *thd, void *sv);
int  (*savepoint_rollback)(THD *thd, void *sv);
int  (*savepoint_release)(THD *thd, void *sv);
```

16.16.5.1. Specifying the Savepoint Offset

The seventh element of the handlerton is the `savepoint_offset`:

```
uint savepoint_offset;
```

The `savepoint_offset` must be initialized statically to the size of the needed memory to store per-savepoint information.

16.16.5.2. Implementing the `savepoint_set` Function

The `savepoint_set()` function is called whenever a user issues the `SAVEPOINT` statement:

```
int  (*savepoint_set)(THD *thd, void *sv);
```

The `*sv` parameter points to an uninitialized storage area of the size defined by `savepoint_offset`.

When `savepoint_set()` is called, the storage engine needs to store savepoint information into `sv` so that the server can later roll back the transaction to the savepoint or release the savepoint resources.

16.16.5.3. Implementing the `savepoint_rollback()` Function

The `savepoint_rollback()` function is called whenever a user issues the `ROLLBACK TO SAVEPOINT` statement:

```
int  (*savepoint_rollback) (THD *thd, void *sv);
```

The `*sv` parameter points to the storage area that was previously passed to the `savepoint_set()` function.

16.16.5.4. Implementing the `savepoint_release()` Function

The `savepoint_release()` function is called whenever a user issues the `RELEASE SAVEPOINT` statement:

```
int  (*savepoint_release) (THD *thd, void *sv);
```

The `*sv` parameter points to the storage area that was previously passed to the `save-`

`point_set()` function.

16.17. Building and Testing Pluggable Storage Engines

With MySQL 5.1 it is possible to build storage engines as shared objects that can be loaded dynamically into a running MySQL server. This new approach makes it easier to deploy custom storage engines because it is no longer necessary to re-compile the MySQL server to install or upgrade a storage engine.

Building and testing a pluggable storage engine requires some modifications to be made to your storage engine source files, along with the creation of a specialized Makefile.

16.17.1. Source Modifications Required to Build a Pluggable Storage Engine

When building a pluggable storage engine, avoid using symbol names that already exist in the `mysqld` source code. This can be as simple as prepending all symbol names with the name of your storage engine.

The following line must be added to the start of your *`storage-engine`*`.cc` file:

```
#include <plugins.h>
```

The `plugins.h` file contains declarations related to the MySQL plugin framework.

Additionally, the following macro must be appended to your *`storage-engine`*`.cc` file:

```
mysql_declare_plugin
{
  MYSQL_STORAGE_ENGINE_PLUGIN,
  &tina_hton,
  tina_hton.name,
  "MySQL AB",
  "CSV Storage Engine",
  tina_init_func, /* Plugin Init */
  tina_done_func  /* Plugin Deinit */
}
mysql_declare_plugin_end;
```

The preceding example is from the `CSV` storage engine.

The first element in the macro declares that this plugin is a storage engine. The second element is a pointer to the storage engine's handlerton. The third element is the name of the plugin. The fourth element is the author of the plugin. The fifth element is a description of the plugin.

The `init` function performs any static initialization required for the plugin, such as creating mutexes and other internal structures.

The `done` function is used to free all resources used by the plugin.

The storage engine should have a `panic` function declared in its handlerton. Upon shutdown of `mysqld`, the panic function is usually passed an argument of value `HA_PANIC_CLOSE`, where the storage engine should close all open tables. However, if the storage engine is a pluggable, and the user attempts to un-install a storage engine at runtime, the value of the panic argument will be `HA_PANIC_TRY_CLOSE`. If the storage engine has any open handler instances, it should return a nonzero fail value, otherwise it should close all files and perform any necessary cleanup.

In the case of a pluggable storage engine, returning a nonzero value from the handlerton `init` function does not prevent the storage engine shared library from being loaded -- only the failure of the

plugin `init` function can prevent loading. However, if the handlerton `init` function returns failure, then the storage engine will be installed in the `DISABLED` state.

16.17.2. Creating a Makefile to Build a Custom Storage Engine

A `Makefile.am` file can be created for your custom storage engine using `Libtool`. The following sample Makefile is for the pluggable version of the `CSV` engine:

```
MYSQLDATAdir =          $(localstatedir)
MYSQLSHAREdir =         $(pkgdatadir)
MYSQLBASEdir=           $(prefix)
MYSQLLIBdir=            $(pkglibdir)
INCLUDES =              -I$(top_srcdir)/include \
                        -I$(top_srcdir)/regex \
                        -I$(top_srcdir)/sql \
                        -I$(srcdir)
WRAPLIBS=

lib_LTLIBRARIES =       libhacsv.la

libhacsv_la_SOURCES =   ha_tina.cc

LDADD =

DEFS =                  -DMYSQL_SERVER @DEFS@

# Don't update the files from bitkeeper %::SCCS/s.%
```

16.17.3. Building a Shared Object

Once the Makefile is created, use the following steps to build a pluggable shared object:

1. Navigate to the directory containing `Makefile.am`.
2. Type `make` to compile the shared object.
3. Type `make install` to install the shared object into the MySQL server's library directory.

16.17.4. Installing a Custom Storage Engine

Once your storage engine is built, ensure the `.so` file is in the MySQL server library directory (typically `installdir/lib`).

To install the plugin, issue the `INSTALL PLUGIN` command:

```
INSTALL PLUGIN ha_foo SONAME
  'ha_foo.so';
```

16.17.5. Uninstalling a Custom Storage Engine

To uninstall a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN ha_foo;
```

If you uninstall a storage engine that is being used by existing tables, those tables will not be accessible, but will still be present on disk (where applicable). Ensure that there are no tables using a given storage engine before uninstalling it otherwise the table will be inaccessible unless you re-install the

storage engine.

16.17.6. Testing a Custom Storage Engine

The MySQL AB development team follows a test-driven approach for storage engine development: as functionality is developed and bugs are fixed, new tests are added to an extensive regression testing suite to ensure that new functionality works properly and old bugs are not re-introduced.

Developers of custom storage engines can use the same regression test suite to ensure the reliable operation of their storage engine.

For more information on the MySQL Test Suite, see Section 27.1.2, “MySQL Test Suite”.

16.17.6.1. Running the Regression Test Suite

To run the test suite follow these steps:

1. From the MySQL main directory tree change directory to the `mysql-test` directory.
2. Run `perl ./mysql-test-run.pl`.

Running the script without options executes the complete test suite on a server running on the local machine.

In order to run a subset of tests or a specific test case, execute `perl ./mysql-test-run.pl --do-test=abc`.This will execute all tests that start with `abc` (`abc*.test`).

For a complete list of options run `perl ./mysql-test-run.pl --help`.

16.17.6.2. Customizing Test Script for Custom Engine Use

The existing tests in the MySQL Test Suite are typically created against specific storage engines. As such, running the full test suite will not result in custom storage engines being tested.

To add support for your storage engine to the test suite, you must first write tests against your storage engine. The simplest way to do this is to take an existing test script and modify the `CREATE TABLE` statements within to use your custom engine.

Tests are located in the `mysql-test/t/`.

For more information on creating and modifying tests, see Section 27.1.2.2, “Extending the MySQL Test Suite”.

16.18. API Reference

16.18.1. bas_ext

Purpose

Defines the file extensions used by the storage engine.

Synopsis

```
virtual const char ** bas_ext ();
;
```

Description

This is the `bas_ext` method. It is called to provide the MySQL server with a list of file extensions used by the storage engine. The list returned is a null-terminated string array.

By providing a list of extensions, storage engines can in many cases omit the `delete_table()` function as the MySQL server will close all references to the table and delete all files with the specified extension.

Parameters

There are no parameters for this function.

Return Values

- Return value is a null-terminated string array of storage engine extensions. The following is an example from the `CSV` engine:

```
static const char *ha_tina_exts[] =
 {
   ".CSV",
   NullS
 };
```

Usage

```
static const char *ha_tina_exts[] =
 {
   ".CSV",
   NullS
 };

const char **ha_tina::bas_ext() const
 {
   return ha_tina_exts;
 }
```

Default Implementation

```
static const char *ha_example_exts[] = {
   NullS
 };

const char **ha_example::bas_ext() const
 {
   return ha_example_exts;
 }
```

16.18.2. close

Purpose

Closes an open table.

Synopsis

```
virtual int close (void);
void ;
```

Description

This is the `close` method.

Closes a table. A good time to free any resources that we have allocated.

Called from sql_base.cc, sql_select.cc, and table.cc. In sql_select.cc it is only used to close up temporary tables or during the process where a temporary table is converted over to being a `MyISAM` table. For sql_base.cc look at close_data_tables().

Parameters

- `void`

Return Values

There are no return values.

Usage

Example from the `CSV` engine:

```
int ha_example::close(void)
{
  DBUG_ENTER("ha_example::close");
  DBUG_RETURN(free_share(share));
}
```

16.18.3. create

Purpose

Creates a new table.

Synopsis

```
virtual int create (name, form, info);
const char *name ;
TABLE *form ;
HA_CREATE_INFO *info ;
```

Description

This is the `create` method.

`create()` is called to create a table. The variable name will have the name of the table. When `create()` is called you do not need to open the table. Also, the `.frm` file will have already been created so `adjusting create_info` is not recommended.

Called from `handler.cc` by `ha_create_table()`.

Parameters

- `name`
- `form`

- info

Return Values

There are no return values.

Usage

Example from the CSV storage engine:

```
int ha_tina::create(const char *name, TABLE *table_arg,
                    HA_CREATE_INFO *create_info)
{
  char name_buff[FN_REFLEN];
  File create_file;
  DBUG_ENTER("ha_tina::create");

  if ((create_file= my_create(fn_format(name_buff, name, "", ".CSV",
                                        MY_REPLACE_EXT|MY_UNPACK_FILENAME),0,
                              O_RDWR | O_TRUNC,MYF(MY_WME))) < 0)
    DBUG_RETURN(-1);

  my_close(create_file,MYF(0));

  DBUG_RETURN(0);
}
```

16.18.4. delete_row

Purpose

Deletes a row.

Synopsis

```
virtual int delete_row (buf);
const byte *buf ;
```

Description

This is the delete_row method.

buf will contain a copy of the row to be deleted. The server will call this right after the current row has been called (from either a previous rnd_next() or index call). If you keep a pointer to the last row or can access a primary key it will make doing the deletion quite a bit easier. Keep in mind that the server does not guarantee consecutive deletions. ORDER BY clauses can be used.

Called in sql_acl.cc and sql_udf.cc to manage internal table information. Called in sql_delete.cc, sql_insert.cc, and sql_select.cc. In sql_select it is used for removing duplicates, while in insert it is used for REPLACE calls.

Parameters

- buf

Return Values

There are no return values.

Usage

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.5. delete_table

Purpose

Delete all files with extension from `bas_ext()`.

Synopsis

```
virtual int delete_table (name);
const char *name ;
```

Description

This is the `delete_table` method.

Used to delete a table. By the time `delete_table()` has been called all opened references to this table will have been closed (and your globally shared references released). The variable name will be the name of the table. You will need to remove any files you have created at this point.

If you do not implement this, the default `delete_table()` is called from `handler.cc`, and it will delete all files with the file extensions returned by `bas_ext()`. We assume that the handler may return more extensions than were actually used for the file.

Called from `handler.cc` by `delete_table` and `ha_create_table()`. Only used during create if the `table_flag` `HA_DROP_BEFORE_CREATE` was specified for the storage engine.

Parameters

- `name`: Base name of table

Return Values

- `0` if we successfully deleted at least one file from `base_ext` and didn't get any other errors than `ENOENT`
- #: Error

Usage

Most storage engines can omit implementing this function.

16.18.6. external_lock

Purpose

Handles table locking for transactions.

Synopsis

```
virtual int external_lock (thd, lock_type);
THD *thd ;
intlock_type ;
```

Description

This is the `external_lock` method.

The “locking functions for mysql” section in `lock.cc` has additional comments on this topic that may be useful to read.

This creates a lock on the table. If you are implementing a storage engine that can handle transactions, look at `ha_berkely.cc` to see how you will want to go about doing this. Otherwise you should consider calling `flock()` here.

Called from `lock.cc` by `lock_external()` and `unlock_external()`. Also called from `sql_table.cc` by `copy_data_between_tables()`.

Parameters

- `thd`
- `lock_type`

Return Values

There are no return values.

Default Implementation

```
{ return 0; }
```

16.18.7. extra

Purpose

Passes hints from the server to the storage engine.

Synopsis

```
virtual int extra (operation);
enum ha_extra_functionoperation ;
```

Description

This is the `extra` method.

`extra()` is called whenever the server wishes to send a hint to the storage engine. The `MyISAM` engine implements the most hints. `ha_innodb.cc` has the most exhaustive list of these hints.

Parameters

- `operation`

Return Values

There are no return values.

Usage

Most storage engines will simply return `0`.

```
{ return 0; }
```

Default Implementation

By default your storage engine can opt to implement none of the hints.

```
{ return 0; }
```

16.18.8. index_end

Purpose

Indicates end of index scan, clean up any resources used.

Synopsis

```
virtual int index_end ();
;
```

Description

This is the `index_end` method. Generally it is used as a counterpart to the `index_init` function, cleaning up any resources allocated for index scanning.

Parameters

This function has no parameters.

Return Values

This function has no return values.

Usage

Clean up all resources allocated, return 0.

Default Implementation

```
{ active_index=MAX_KEY; return 0; }
```

16.18.9. index_first

Purpose

Retrieve first row in index and return.

Synopsis

```
virtual int index_first (buf);
byte *buf ;
```

Description

This is the `index_first` method.

`index_first()` asks for the first key in the index.

Called from opt_range.cc, opt_sum.cc, sql_handler.cc, and sql_select.cc.

Parameters

- `buf` - byte array to be populated with row.

Return Values

There are no return values.

Usage

Implementation depends on indexing method used.

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.10. index_init

Purpose

Signals the storage engine that an index scan is about to occur. Storage engine should allocate any resources needed.

Synopsis

```
virtual int index_init (idx, sorted);
uint idx ;
bool sorted ;
```

Description

This is the `index_init` method. This function is called before an index scan, allowing the storage engine to allocate resources and make preparations.

Parameters

- `idx`
- `sorted`

Return Values

-

Usage

This function can typically just return 0 if there is no preparation needed.

Default Implementation

```
{ active_index=idx; return 0; }
```

16.18.11. index_last

Purpose

Return the last row in the index.

Synopsis

```
virtual int index_last (buf);
byte *buf ;
```

Description

This is the `index_last` method.

`index_last()` asks for the last key in the index.

Called from opt_range.cc, opt_sum.cc, sql_handler.cc, and sql_select.cc.

Parameters

- `buf` - byte array to be populated with matching row.

Return Values

This function has no return values.

Usage

Advance to last row in index and return row in buffer.

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.12. index_next

Purpose

Return next row in index.

Synopsis

```
virtual int index_next (buf);
byte *buf ;
```

Description

This is the `index_next` method.

Used to read forward through the index.

Parameters

- `buf`

Return Values

This function has no return values.

Usage

Advance to next row in index using pointer or cursor, return row in buffer.

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.13. index_prev

Purpose

Advance to previous row in index.

Synopsis

```
virtual int index_prev (buf);
byte *buf ;
```

Description

This is the `index_prev` method.

Used to read backward through the index.

Parameters

- `buf`

Return Values

This function has no return values.

Usage

Move to previous row in index, retun in buffer.

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.14. index_read_idx

Purpose

Find a row based on a key and return.

Synopsis

```
virtual int index_read_idx (buf, index, key, key_len, find_flag);
byte *buf ;
uintindex ;
const byte *key ;
uintkey_len ;
enum ha_rkey_functionfind_flag ;
```

Description

This is the `index_read_idx` method.

Positions an index cursor to the index specified in key. Fetches the row if any. This is only used to read whole keys.

Parameters

- `buf`
- `index`
- `key`
- `key_len`
- `find_flag`

Return Values

This function has no return values.

Usage

Locate the row that matches the key passed and return it in the buffer provided.

16.18.15. index_read

Purpose

Find a row based on a key and return.

Synopsis

```
virtual int index_read (buf, key, key_len, find_flag);
byte *buf ;
const byte *key ;
uintkey_len ;
enum ha_rkey_functionfind_flag ;
```

Description

This is the `index_read` method.

Positions an index cursor to the index specified in the handle. Fetches the row if available. If the key value is null, begin at the first key of the index.

Parameters

- `buf`
- `key`
- `key_len`
- `find_flag`

Return Values

This function has no return values.

Usage

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.16. info

Purpose

Prompts storage engine to report statistics.

Synopsis

```
virtual void info (uint);
uint ;
```

Description

This is the `info` method.

::info() is used to return information to the optimizer. Currently this table handler doesn't implement

most of the fields really needed. SHOW also makes use of this data Another note, you will probably want to have the following in your code: if (records < 2) records = 2; The reason is that the server will optimize for cases of only a single record. If in a table scan you don't know the number of records it will probably be better to set records to two so you can return as many records as you need. Along with records a few more variables you may wish to set are: records deleted data_file_length index_file_length delete_length check_time See public variables in handler.h for more information.

Called in: filesort.cc ha_heap.cc item_sum.cc opt_sum.cc sql_delete.cc sql_delete.cc sql_derived.cc sql_select.cc sql_select.cc sql_select.cc sql_select.cc sql_select.cc sql_show.cc sql_show.cc sql_show.cc sql_show.cc sql_table.cc sql_union.cc sql_update.cc

Parameters

- `uint`

Return Values

There are no return values.

Usage

This example is from the `CSV` storage engine:

```
void ha_tina::info(uint flag)
{
  DBUG_ENTER("ha_tina::info");
  /* This is a lie, but you don't want the optimizer to see zero or 1 */
  if (records < 2)
    records= 2;
  DBUG_VOID_RETURN;
}
```

16.18.17. open

Purpose

Opens a table.

Synopsis

```
virtual int open (name, mode, test_if_locked);
const char *name ;
intmode ;
uinttest_if_locked ;
```

Description

This is the `open` method.

Used for opening tables. The name will be the name of the file. A table is opened when it needs to be opened. For instance when a request comes in for a select on the table (tables are not open and closed for each request, they are cached).

Called from handler.cc by handler::ha_open(). The server opens all tables by calling ha_open() which then calls the handler specific open().

A handler object is opened as part of its initialization and before being used for normal queries (not before meta-data changes always.) If the object was opened it will also be closed before being de-

leted.

This is the `open` method. `open` is called to open a database table.

The first parameter is the name of the table to be opened. The second parameter determines what file to open or what operation to take. The values are defined in `handler.h` and are copied here for your convenience:

```
#define HA_OPEN_KEYFILE           1
#define HA_OPEN_RNDFILE           2
#define HA_GET_INDEX             4
#define HA_GET_INFO               8     /* do a ha_info() after open */
#define HA_READ_ONLY             16   /* File opened as readonly */
#define HA_TRY_READ_ONLY   32    /* Try readonly if can't open with rea
#define HA_WAIT_IF_LOCKED   64   /* Wait if locked on open */
#define HA_ABORT_IF_LOCKED 128   /* skip if locked on open.*/
#define HA_BLOCK_LOCK             256   /* unlock when reading some rec
#define HA_OPEN_TEMPORARY   512
```

The final option dictates whether the handler should check for a lock on the table before opening it.

Typically your storage engine will need to implement some form of shared access control to prevent file corruption is a multi-threaded environment. For an example of how to implement file locking, see the `get_share()` and `free_share()` methods of `sql/examples/ha_tina.cc`.

Parameters

- `name`
- `mode`
- `test_if_locked`

Return Values

There are no return values.

Usage

This example is from the `CSV` storage engine:

```
int ha_tina::open(const char *name, int mode, uint test_if_locked)
{
DBUG_ENTER("ha_tina::open");

if (!(share= get_share(name, table)))
DBUG_RETURN(1);
thr_lock_data_init(&share->lock,&lock,NULL);
ref_length=sizeof(off_t);

DBUG_RETURN(0);
}
```

16.18.18. position

Purpose

Provide the MySQL server with position/offset information for last-read row.

Synopsis

```
virtual void position (record);
const byte *record ;
```

Description

This is the `position` method.

position() is called after each call to rnd_next() if the data needs to be ordered. You can do something like the following to store the position: my_store_ptr(ref, ref_length, current_position);

The server uses ref to store data. ref_length in the above case is the size needed to store current_position. ref is just a byte array that the server will maintain. If you are using offsets to mark rows, then current_position should be the offset. If it is a primary key like in `BDB`, then it needs to be a primary key.

Called from filesort.cc, sql_select.cc, sql_delete.cc and sql_update.cc.

Parameters

- `record`

Return Values

This function has no return values.

Usage

Return offset or retrieval key information for last row.

16.18.19. records_in_range

Purpose

For the given range how many records are estimated to be in this range.

Synopsis

```
virtual ha_rows records_in_range (inx, min_key, max_key);
uintinx ;
key_range *min_key ;
key_range *max_key ;
```

Description

This is the `records_in_range` method.

Given a starting key, and an ending key estimate the number of rows that will exist between the two. end_key may be empty which in case determine if start_key matches any rows.

Used by optimizer to calculate cost of using a particular index.

Called from opt_range.cc by check_quick_keys().

Parameters

- `inx`
- `min_key`
- `max_key`

Return Values

Return the approxamite number of rows.

Usage

Determine an approxamite count of the rows between the key values and return.

Default Implementation

```
{ return (ha_rows) 10; }
```

16.18.20. rnd_init

Purpose

Initializes a handler for table scanning.

Synopsis

```
virtual int rnd_init (scan);
boolscan ;
```

Description

This is the `rnd_init` method.

rnd_init() is called when the system wants the storage engine to do a table scan.

Unlike index_init(), rnd_init() can be called two times without rnd_end() in between (it only makes sense if scan=1). then the second call should prepare for the new table scan (e.g if rnd_init allocates the cursor, second call should position it to the start of the table, no need to deallocate and allocate it again

Called from filesort.cc, records.cc, sql_handler.cc, sql_select.cc, sql_table.cc, and sql_update.cc.

Parameters

- `scan`

Return Values

There are no return values.

Usage

This example is from the `CSV` storage engine:

```
int ha_tina::rnd_init(bool scan)
{
  DBUG_ENTER("ha_tina::rnd_init");

  current_position= next_position= 0;
  records= 0;
  chain_ptr= chain;
  DBUG_RETURN(0);
}
```

16.18.21. rnd_next

Purpose

Reads the next row from a table and returns it to the server.

Synopsis

```
virtual int rnd_next (buf);
byte *buf ;
```

Description

This is the `rnd_next` method.

This is called for each row of the table scan. When you run out of records you should return HA_ERR_END_OF_FILE. Fill buff up with the row information. The Field structure for the table is the key to getting data into buf in a manner that will allow the server to understand it.

Called from filesort.cc, records.cc, sql_handler.cc, sql_select.cc, sql_table.cc, and sql_update.cc.

Parameters

- `buf`

Return Values

There are no return values.

Usage

This example is from the `ARCHIVE` storage engine:

```
int ha_archive::rnd_next(byte *buf)
{
  int rc;
  DBUG_ENTER("ha_archive::rnd_next");

  if (share->crashed)
      DBUG_RETURN(HA_ERR_CRASHED_ON_USAGE);

  if (!scan_rows)
    DBUG_RETURN(HA_ERR_END_OF_FILE);
  scan_rows--;

  statistic_increment(table->in_use->status_var.ha_read_rnd_next_count,
                      &LOCK_status);
    current_position= gztell(archive);
  rc= get_row(archive, buf);
```

```
if (rc != HA_ERR_END_OF_FILE)
```

Description

This is the `start_stmt` method.

When table is locked a statement is started by calling start_stmt instead of external_lock

Parameters

- `thd`
- `lock_type`

Return Values

This function has no return values.

Usage

Make any preparations needed for a transaction start (if there is no current running transaction).

Default Implementation

```
{return 0;}
```

16.18.24. store_lock

Purpose

Creates and releases table locks.

Synopsis

```
virtual THR_LOCK_DATA ** store_lock (thd, to, lock_type);
THD *thd ;
THR_LOCK_DATA **to ;
enum thr_lock_typelock_type ;
```

Description

This is the `store_lock` method.

The idea with handler::store_lock() is the following:

The statement decided which locks we should need for the table for updates/deletes/inserts we get WRITE locks, for SELECT... we get read locks.

Before adding the lock into the table lock handler `mysqld` calls store lock with the requested locks. Store lock can modify the lock level, e.g. change blocking write lock to non-blocking, ignore the lock (if we don't want to use MySQL table locks at all) or add locks for many tables (like we do when we are using a MERGE handler).

Berkeley DB for example, downgrades blocking table TL_WRITE locks to non-blocking TL_WRITE_ALLOW_WRITE locks (which signals that we are doing WRITES, but we are still allowing other readers and writers).

When releasing locks, store_lock() are also called. In this case one usually doesn't have to do any-

thing.

If the argument of store_lock is TL_IGNORE, it means that MySQL requests the handler to store the same lock level as the last time.

Called from lock.cc by get_lock_data().

Parameters

- `thd`
- `to`
- `lock_type`

Return Values

There are no return values.

Usage

The following example is from the `ARCHIVE` storage engine:

```
/*
  Below is an example of how to setup row level locking.
*/
THR_LOCK_DATA **ha_archive::store_lock(THD *thd,
                                       THR_LOCK_DATA **to,
                                       enum thr_lock_type lock_type)
{
  if (lock_type == TL_WRITE_DELAYED)
    delayed_insert= TRUE;
  else
    delayed_insert= FALSE;

  if (lock_type != TL_IGNORE && lock.type == TL_UNLOCK)
  {
    /*
      Here is where we get into the guts of a row level lock.
      If TL_UNLOCK is set
      If we are not doing a LOCK TABLE or DISCARD/IMPORT
      TABLESPACE, then allow multiple writers
    */

    if ((lock_type >= TL_WRITE_CONCURRENT_INSERT &&
         lock_type <= TL_WRITE) && !thd->in_lock_tables
        && !thd->tablespace_op)
      lock_type = TL_WRITE_ALLOW_WRITE;

    /*
      In queries of type INSERT INTO t1 SELECT ... FROM t2 ...
      MySQL would use the lock TL_READ_NO_INSERT on t2, and that
      would conflict with TL_WRITE_ALLOW_WRITE, blocking all inserts
      to t2. Convert the lock to a normal read lock to allow
      concurrent inserts to t2.
    */

    if (lock_type == TL_READ_NO_INSERT && !thd->in_lock_tables)
      lock_type = TL_READ;

    lock.type=lock_type;
  }

  *to++= &lock;
```

```
  return to;
}
```

The following is the minimal implementation, for a storage engine that does not need to downgrade locks:

```
THR_LOCK_DATA **ha_tina::store_lock(THD *thd,
                                   THR_LOCK_DATA **to,
                                   enum thr_lock_type lock_type)
{
   /* Note that if the lock type is TL_IGNORE we don't update lock.type,
      preserving the previous lock level */
   if (lock_type != TL_IGNORE && lock.type == TL_UNLOCK)
     lock.type=lock_type;
    /* the heart of the store_lock() method and it's main purpose -
      storing the (possibly changed) lock level into the provided
      memory */
     *to++= &lock;
     return to;
}
```

See also ha_berkeley::store_lock() and ha_myisammrg::store_lock() for more complex implementation

16.18.25. update_row

Purpose

Updates the contents of an existing row.

Synopsis

```
virtual int update_row (old_data, new_data);
const byte *old_data ;
byte *new_data ;
```

Description

This is the `update_row` method.

old_data will have the previous row record in it, while new_data will have the newest data in it.

The server can do updates based on ordering if an ORDER BY clause was used. Consecutive ordering is not guaranteed.

Currently new_data will not have an updated auto_increament record, or and updated timestamp field. You can do these for example by doing these: if (table->timestamp_field_type & TIMESTAMP_AUTO_SET_ON_UPDATE) table->timestamp_field->set_time(); if (table->next_number_field && record == table->record[0]) update_auto_increment();

Called from sql_select.cc, sql_acl.cc, sql_update.cc, and sql_insert.cc.

Parameters

- `old_data`
- `new_data`

Return Values

There are no return values.

Usage

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

16.18.26. write_row

Purpose

Adds a new row to a table.

Synopsis

```
virtual int write_row (buf);
byte *buf ;
```

Description

This is the `write_row` method.

`write_row()` inserts a row. No `extra()` hint is given currently if a bulk load is happening. buf is a byte array of data with a size of table->s->reclength

You can use the field information to extract the data from the native byte array type. Example of this would be: for (Field **field=table->field ; *field ; field++) { ... }

BLOBs must be handled specially:

```
for (ptr= table->s->blob_field, end= ptr + table->s->blob_fields ; ptr != end ;
  {
        char *data_ptr;
        uint32 size= ((Field_blob*)table->field[*ptr])->get_length();
        ((Field_blob*)table->field[*ptr])->get_ptr(&data_ptr);
        ...
  }
```

See ha_tina.cc for an example of extracting all of the data as strings. ha_berkeley.cc has an example of how to store it intact by "packing" it for ha_berkeley's own native storage type.

See the note for `update_row()` on auto_increments and timestamps. This case also applied to write_row().

Called from item_sum.cc, item_sum.cc, sql_acl.cc, sql_insert.cc, sql_insert.cc, sql_select.cc, sql_table.cc, sql_udf.cc, and sql_update.cc.

Parameters

- `buf` byte array of data

Return Values

There are no return values.

Usage

Default Implementation

```
{ return  HA_ERR_WRONG_COMMAND; }
```

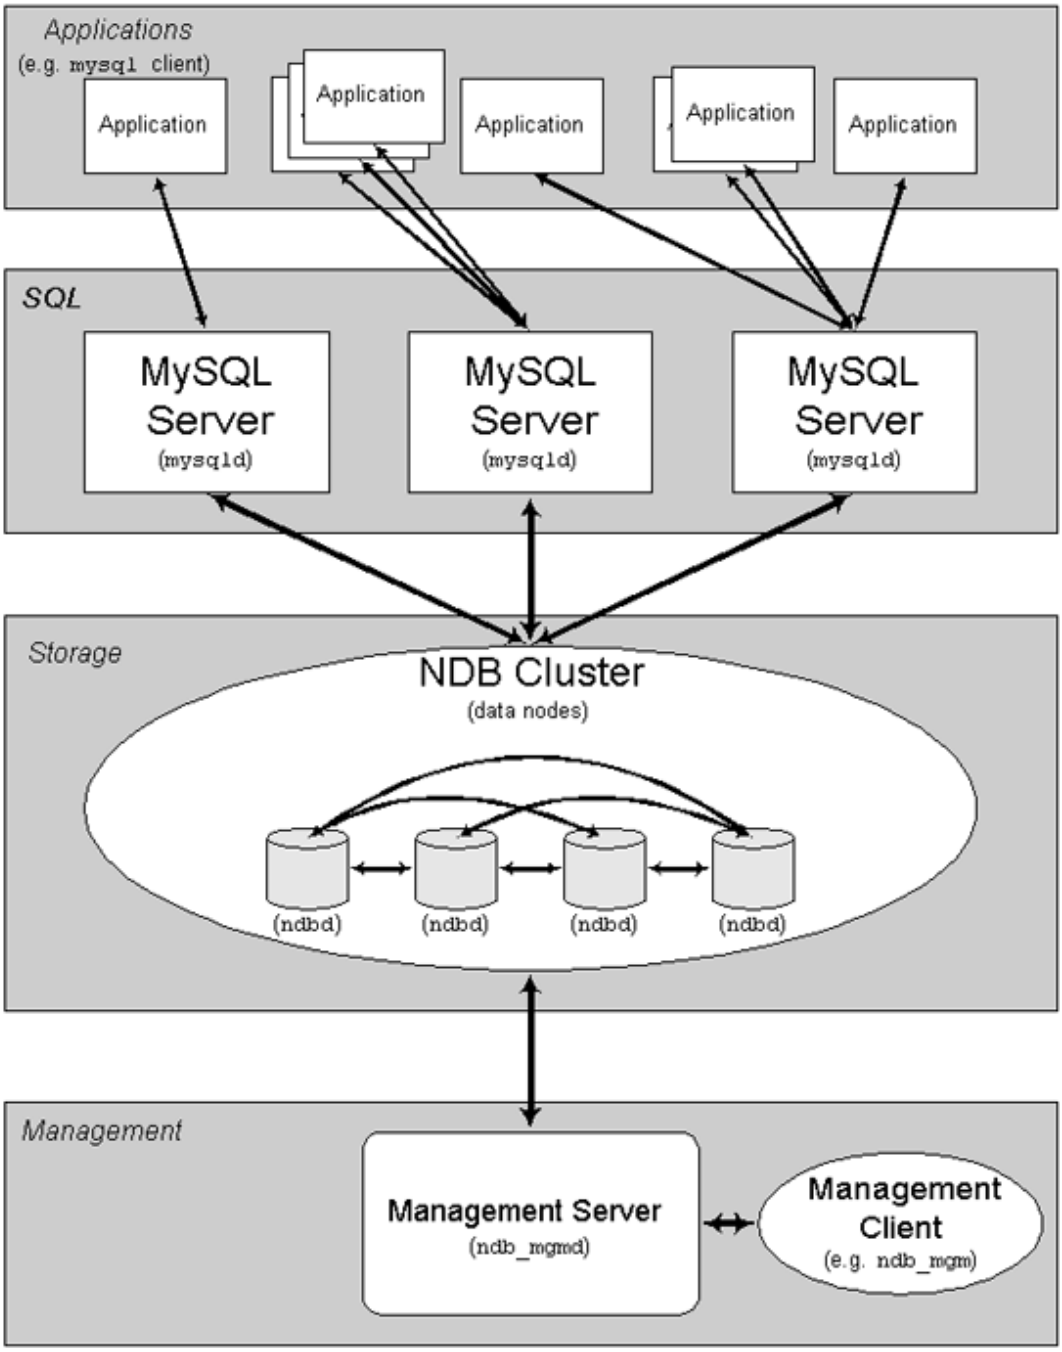
Chapter 17. MySQL Cluster

MySQL Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the `NDB Cluster` storage engine to enable running several MySQL servers in a cluster. This storage engine is available in MySQL 5.1 binary releases and in RPMs compatible with most modern Linux distributions. (Note that both the `mysql-server` and `mysql-max` RPMs must be installed in order to have MySQL Cluster capability.)

The operating systems on which MySQL Cluster is currently available are Linux, Mac OS X, and Solaris. (Some users have reported success with running MySQL Cluster on FreeBSD, although this is not yet officially supported by MySQL AB.) We are working to make Cluster run on all operating systems supported by MySQL, including Windows, and will update this page as new platforms are supported.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at http://www.mysql.com/products/cluster/.

Additional resources



- Answers to some commonly asked questions about Cluster may be found in the Section 17.10, “MySQL Cluster FAQ”.
- The MySQL Cluster mailing list: http://lists.mysql.com/cluster.
- The MySQL Cluster forum: http://forums.mysql.com/list.php?25.
- If you are new to MySQL Cluster, you may find our Developer Zone article How to set up a MySQL Cluster for two servers [http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html] to be helpful.

17.1. MySQL Cluster Overview

MySQL Cluster is a technology which enables clustering of in-memory databases in a share-nothing system. The share-nothing architecture allows the system to work with very inexpensive hardware, and without any specific requirements on hardware or software. It also does not have any single point of failure because each component has its own memory and disk.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called `NDB`. In our documentation, the term `NDB` refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of MySQL and the `NDB` storage engine.

A MySQL Cluster consists of a set of computers, each running a number of processes including MySQL servers, data nodes for NDB Cluster, management servers, and (possibly) specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the NDB Cluster storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Since transactional applications are expected to handle transaction failure, this should not be a source of problems.

By bringing MySQL Cluster to the Open Source world, MySQL makes clustered data management with high availability, high performance, and scalability available to all who need it.

17.2. Basic MySQL Cluster Concepts

NDB is an in-memory storage engine offering high-availability and data-persistence features.

The NDB storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

We will now describe how to set up a MySQL Cluster consisting of an NDB storage engine and some MySQL servers.

The cluster portion of MySQL Cluster is currently configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a **node**.

Note: In many contexts, the term "node" is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. There can be any number of nodes on a single computer, for which we use the term **cluster host**.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- The management (`MGM`) node: The role of this type of node is to manage the other nodes within the MySQL Cluster, such as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- The **data node**: This is the type of node that stores the cluster's data. There are as many data nodes as there are replicas, times the number of fragments. For example, with two replicas, each having two fragments, you will need four data nodes. It is not necessary to have more than one replica. A data node is started with the command `ndbd`.

- The **SQL node**: This is the node that accesses the cluster data. In the case of MySQL Cluster, a client node is a traditional MySQL server that uses the NDB Cluster storage engine. An SQL node is typically started with the command `mysqld --ndbcluster` or simply by using `mysqld` with `ndbcluster` added to `my.cnf`.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that storage nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, in order to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

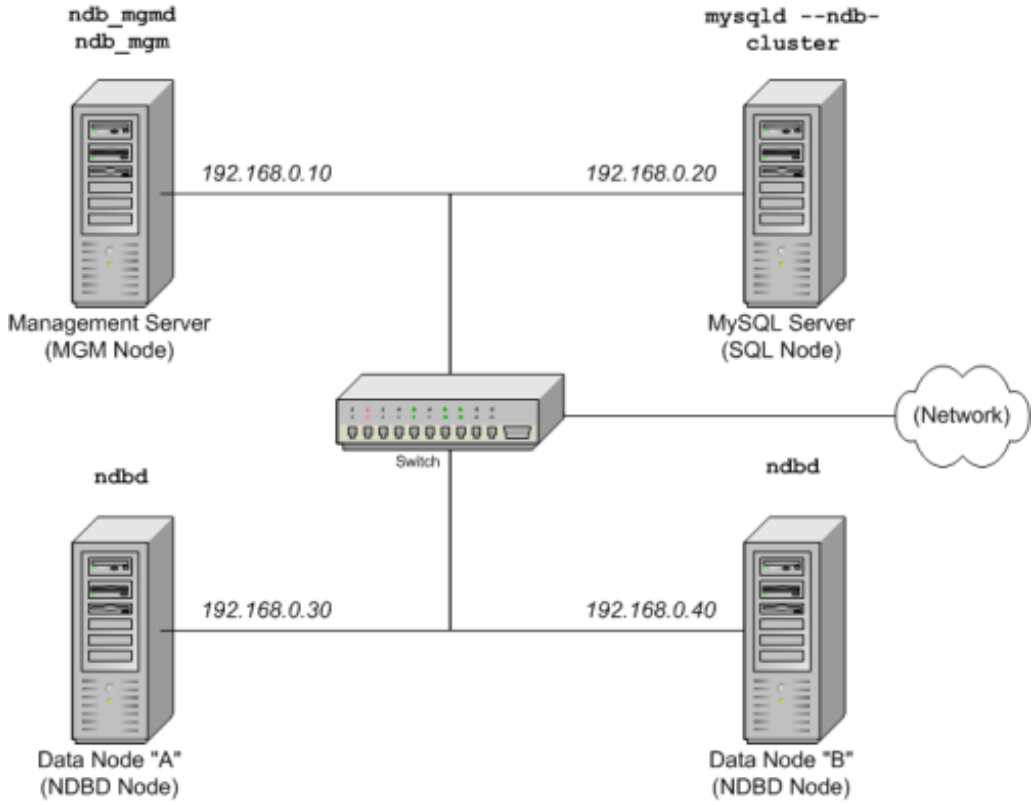
- **Standard MySQL clients**: These are no different for MySQL Cluster than they are for standard (non-Cluster) MySQL. In other words, MySQL Cluster can be accessed from existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on.

- **Management clients**: These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on.

17.3. Simple Multi-Computer How-To

This section is a “How-To” in which we describe the basics for how to plan, install, configure, and run a MySQL Cluster. Unlike the example in Section 17.4, “MySQL Cluster Configuration”, the result of following the guidelines and procedures outlined below should be a usable MySQL Cluster which meets minimum requirements for availability and safeguarding of data.

In this section, we will cover hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.



Basic Assumptions

This How-To makes the following assumptions:

1. We are setting up our cluster with 4 nodes, each on a separate host, and each with a fixed network address on a typical Ethernet as shown here:

Node	IP Address
Management (MGM) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

This may be made clearer in the following diagram:

Note: In the interest of simplicity (and reliability), we will use only numeric IP addresses in this How-To. However, if DNS resolution is available on your network, then it is possible to use hostnames in lieu of IP addresses in configuring Cluster. Alternatively, you can also use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host lookup if such is available.

2. Each host in our scenario is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and running no unnecessary services. The core OS with a standard TCP/IP networking client should be sufficient. Also for the sake of simplicity, we also assume that the filesystems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions accordingly.

3. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all 4 hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughout; that is, all 4 machines in the cluster should have 100 Mbps cards *or* all 4 machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, gigabit Ethernet will provide better performance.

   Note that MySQL Cluster is *not* intended for use in a network whose connectivity is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

4. For our sample data, we will use the `world` database which is available for download from the MySQL AB Web site. As this database takes up a relatively small amount of space, we assume that each machine has 256 MB RAM, which should be sufficient for running the operating system, host NDB process, and (for the data nodes) for storing the database.

Although we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to either Solaris or Mac OS X. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See Section 17.3.1, “Hardware, Software, and Networking”.)

17.3.1. Hardware, Software, and Networking

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (Note that this is subject to change, and that we intend to implement disk-based storage in a future MySQL Cluster release.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For Mac OS X or Solaris, the standard installation is sufficient. For Linux, a standard, “out of the box” installation should be all that is necessary. The MySQL software requirements are simple: all that is needed is a production release of MySQL-max 5.1; you must use the `-max` version of MySQL in order to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this How-To, we assume that you are using the `-max` binary appropriate to your Linux, Solaris, or Mac OS X operating system, available via the MySQL software downloads page at http://dev.mysql.com/downloads/.

For inter-node communication, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- **Security**: Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ [http://compnetworking.about.com/cs/networksecurity/g/bldef_dmz.htm]) or elsewhere.

- **Efficiency**: Setting up a MySQL Cluster on a private or protected network allows for the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Section 17.7, “Using High-Speed Interconnects with MySQL Cluster”, for more about this protocol and its use with MySQL Cluster.

17.3.2. Installation

Each MySQL Cluster host computer running storage or SQL nodes must have installed on it a MySQL-max binary. For management nodes, it is not necessary to install the MySQL server binary, but you do have to install the MGM server daemon and client binaries (`ndb_mgmd` and `ndb_mgm`, respectively). In this section, we will cover the steps necessary to install the correct binaries for each type of Cluster node.

MySQL AB provides precompiled binaries which support Cluster, and there is generally no need to compile these yourself. (If you do require a custom binary, see Section 2.8.3, “Installing from the Development Source Tree”.) Therefore, the first step in the installation process for each cluster host is to download the file `mysql-max-5.1.5-alpha-pc-linux-gnu-i686.tar.gz` from the MySQL downloads area [http://dev.mysql.com/downloads/]. We assume that you have placed it in each machine's `/var/tmp` directory.

RPMs are also available for both 32-bit and 64-bit Linux platforms; the `-max` binaries installed by the RPMs support the `NDBCluster` storage engine. If you choose to use these rather than the binary files, be aware that you must install *both* the `-server` and `-max` packages on all machines that are to host cluster nodes. (See Section 2.4, “Installing MySQL on Linux”, for more information about installing MySQL using the RPMs.) After installing from RPM, you will still need to configure the cluster as discussed in Section 17.3.3, “Configuration”.

Note: After completing the installation, do not yet start any of the binaries. We will show you how to do so following the configuration of all nodes.

Storage and SQL Node Installation

On each of the 3 machines designated to host storage or SQL nodes, perform the following steps as the system root user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for manging users and groups) to see whether or not there are already a `mysql` group and `mysql` user on the system, as some OS distributions create these as part of the operating system installation process. If these are not already present, then create a new `mysql` user group, then add a `mysql` user to this group:

   ```
   groupadd mysql
   useradd -g mysql mysql
   ```

2. Change to the directory containing the downloaded file; unpack the archive; create a symlink to the mysql-max executable. Note that the actual file and directory names will vary according to the MySQL version number.

   ```
   cd /var/tmp
   tar -xzvf -C /usr/local/bin mysql-max-5.1.5-alpha-pc-linux-gnu-i686.tar.gz
   ln -s /usr/local/bin/mysql-max-5.1.5-alpha-pc-linux-gnu-i686 mysql
   ```

3. Change to the `mysql` directory, and run the supplied script for creating the system databases:

```
cd mysql
scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
chown -R root .
chown -R mysql data
chgrp -R mysql .
```

   Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. We will make use of this piece of information when we configure the management node. (See Section 17.3.3, “Configuration”.)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
cp support-files/mysql.server /etc/rc.d/init.d/
chmod +x /etc/rc.d/init.d/mysql.server
chkconfig --add mysql.server
```

   Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system/distribution, such as `update-rc.d` on Debian.

Remember that the steps listed above must be performed separately for each machine on which a storage or SQL node is to reside.

Management Node Installation

For the MGM (management) node, it is not necessary to install the `mysqld` executable, only the binaries for the MGM server and client, which can be found in the downloaded `-max` archive. Again we assume that you have placed this file in `/var/tmp`. As system root (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Move to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
cd /var/tmp
tar -zxvf mysql-max-5.1.5-alpha-pc-linux-gnu-i686.tar.gz /usr/local/bin '*/b
```

2. Move to the directory into which you unpacked the files, and then make both of these executable:

```
cd /usr/local/bin
chmod +x ndb_mgm*
```

In Section 17.3.3, “Configuration”, we will create and write configuration files for all of the nodes in our example Cluster.

17.3.3. Configuration

For our 4-node, 4-host MySQL Cluster, we will need to write 4 configuration files, 1 per node/host.

- Each data node or SQL node will require a `my.cnf` file that provides two pieces of information: a **connectstring** telling the node where to find the MGM node, and a line telling the MySQL server on this host (the machine hosting the data node) to run in NDB mode.

  For more information on connectstrings, see Section 17.4.4.2, “The MySQL Cluster `connectstring`”.

- The management node will need a `config.ini` file telling it how many replicas are to be maintained, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where data will be saved to disk on each data node, and where to find any SQL nodes.

Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited (and created if necessary) using any text editor, for example:

```
vi /etc/my.cnf
```

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
# Options for mysqld process:
[MYSQLD]
ndbcluster                      # run NDB engine
ndb-connectstring=192.168.0.10  # location of MGM node

# Options for ndbd process:
[MYSQL_CLUSTER]
ndb-connectstring=192.168.0.10  # location of MGM node
```

After entering the above, save this file and exit the text editor. Do this for the machines hosting data node "A", data node "B", and the SQL node.

Configuring the Management Node

The first step in configuring the MGM node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```
mkdir /var/lib/mysql-cluster
cd /var/lib/mysql-cluster
vi config.ini
```

We show `vi` being used here to create the file, but any text editor should work just as well.

For our representative setup, the `config.ini` file should read as follows:

```
# Options affecting ndbd processes on all data nodes:
[NDBD DEFAULT]
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage
IndexMemory=18M   # How much memory to allocate for index storage
                  # For DataMemory and IndexMemory, we have used the
                  # default values. Since the "world" database takes up
                  # only about 500KB, this should be more than enough for
                  # this example Cluster setup.

# TCP/IP options:
[TCP DEFAULT]
portnumber=2202   # This the default; however, you can use any
                  # port that is free for all the hosts in cluster
                  # Note: It is recommended beginning with MySQL 5.0 that
```

```
                  # you do not specify the portnumber at all and simply allow
                  # the default value to be used instead

# Management process options:
[NDB_MGMD]
hostname=192.168.0.10           # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster  # Directory for MGM node logfiles

# Options for data node "A":
[NDBD]
                                # (one [NDBD] section per data node)
hostname=192.168.0.30           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's datafiles

# Options for data node "B":
[NDBD]
hostname=192.168.0.40           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's datafiles

# SQL node options:
[MYSQLD]
hostname=192.168.0.20           # Hostname or IP address
                                # (additional mysqld connections can be
                                # specified for this node for various
                                # purposes such as running ndb_restore)
```

(**NOTE**: The "world" database can be downloaded from http://dev.mysql.com/doc/ where it can be found listed under "Examples".)

Once all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 17.3.4, “Initial Startup”.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 17.4.4, “Configuration File”, and Section 17.4, “MySQL Cluster Configuration”. For configuration of MySQL Cluster as relates to making backups, see Section 17.6.5.4, “Configuration for Cluster Backup”.

Note: The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. Beginning with MySQL 5.0.3, this restriction is lifted, and the cluster will automatically allocate ports for data nodes from those that are already free.

17.3.4. Initial Startup

Starting the cluster is not very difficult once it has been configured. Each cluster node process must be started separately, and on the host where it resides. Although it is possible to start the nodes in any order, it is recommended that the management node be started first, followed by the storage nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the MGM node process:

   ```
   shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
   ```

   Note that `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 17.5.3, “`ndb_mgmd`, the Management Server Process”, for details.)

2. On each of the data node hosts, run this command to start the NDBD process for the first time:

   ```
   shell> ndbd --initial
   ```

Note that it is very important to use the `--initial` parameter **only** when starting `ndbd` for the first time, or when restarting after backup/restore or configuration change. This is because this parameter will cause the node to delete any files created by earlier `ndbd` instances needed for recovery, including the recovery log files.

3. If you have used the RPMs to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the startup script installed to `/etc/init.d` to start the MySQL server process on the SQL node. Note that you need to install the `-max` server RPM *in addition to* the Standard server RPM in order to run the `-max` server binary.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client; the output should look like what is shown below:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @192.168.0.30  (Version: 5.1.5-alpha, Nodegroup: 0, Master)
id=3    @192.168.0.40  (Version: 5.1.5-alpha, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @192.168.0.10  (Version: 5.1.5-alpha)

[mysqld(SQL)]   1 node(s)
id=4   (Version: 5.1.5-alpha)
```

You may see some slight differences in the output depending upon the exact version of MySQL that you are using.

Note: If you are using an older version of MySQL, you may see the SQL node referenced as '`[mysqld(API)]`'. This reflects an older usage which is now deprecated.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See Section 17.3.5, "Loading Sample Data and Performing Queries", for a brief discussion.

17.3.5. Loading Sample Data and Performing Queries

Working with data in MySQL Cluster is not much different than working with it MySQL without Cluster. There are two points to keep in mind when doing so:

- Tables must be created with the `ENGINE=NDB` or `ENGINE=NDBCLUSTER` option, or be altered (using `ALTER TABLE`) to use the NDB CLuster storage engine in order to have them replicated in the cluster. If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script or scripts in a text editor and add this option to any table creation statements, or replace any existing `ENGINE` (or `TYPE`) option with one of these. For example, suppose that you have the sample `world` database on another MySQL server (that does not support MySQL Cluster), and you wish to export the definition for the `City` table:

  ```
  shell> mysqldump --add-drop-table world City > city_table.sql
  ```

  The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

  ```
  DROP TABLE IF EXISTS City;
  CREATE TABLE City (
  ID int(11) NOT NULL auto_increment,
  ```

```
Name char(35) NOT NULL default '',
CountryCode char(3) NOT NULL default '',
District char(20) NOT NULL default '',
Population int(11) NOT NULL default '0',
PRIMARY KEY  (ID)
) ENGINE=MyISAM;

INSERT INTO City VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO City VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO City VALUES (3,'Herat','AFG','Herat',186800);
# (remaining INSERT statements omitted)
```

You will need to make sure that MySQL uses the NDB storage engine for this table. There are two ways that this can be accomplished. One of these is, *before* importing the table into the Cluster database, to modify its definition so that it reads (still using `City` as an example):

```
DROP TABLE IF EXISTS City;
CREATE TABLE City (
ID int(11) NOT NULL auto_increment,
Name char(35) NOT NULL default '',
CountryCode char(3) NOT NULL default '',
District char(20) NOT NULL default '',
Population int(11) NOT NULL default '0',
PRIMARY KEY  (ID)
) ENGINE=NDBCLUSTER;

INSERT INTO City VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO City VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO City VALUES (3,'Herat','AFG','Herat',186800);
# (etc.)
```

This will need to be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is simply to do a search-and-replace on the `world.sql` file and replace all instances of `TYPE=MyISAM` or `ENGINE=MyISAM` with `ENGINE=NDBCLUSTER`. If you do not wish to modify the file, you can also use `ALTER TABLE`; see below for particulars.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the above command must be executed on the host where the SQL node is running -- in this case, on the machine with the IP address **192.168.0.20**.

To create a copy of the `world` database on the SQL node, save the file to `/usr/local/mysql/data`, then run

```
shell> cd /usr/local/mysql/data
shell> mysql world < world.sql
```

Of course, the SQL script must be readable by the `mysql` system user. If you save the file to a different location, adjust the above accordingly.

It is important to note that `NDB Cluster` in MySQL 5.1 does not support autodiscovery of databases. (See Section 17.8, “Known Limitations of MySQL Cluster”.) This means that, once the `world` database and its tables have been created on one data node, you need to issue the statement `CREATE SCHEMA world;`, followed by `FLUSH TABLES;` on each SQL node in the cluster. This will cause the node to recognize the database and read its table definitions.

Running SELECT queries on the SQL node is no different than running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way:

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.5-alpha

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

If you did not modify the ENGINE= clauses in the table definitions prior to importing the SQL script, you should run the following commands at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Note that we simply use the MySQL server's default root account with its empty password here. Of course, in a production setting, you should *always* follow the standard security precautions for installing a MySQL server, including the setting of a strong root password and creation of a user account with only those privileges required to accomplish the tasks necessary for that user. For more information about these, see Section 5.7, “The MySQL Access Privilege System”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privileges system when accessing one another, and setting or changing MySQL user accounts (including the root account) has no effect on interaction between nodes, only on applications accessing the SQL node.

Selecting a database and running a SELECT query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
+-----------+------------+
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications using MySQL can use standard APIs. It is important to remember that your application must access the SQL node, and not the MGM or storage nodes. This brief example shows how we might execute the same query as above using PHP 5's mysqli extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
  "http://www.w3.org/TR/html4/loose.dtd">
<html>
```

```
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', '', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
  <tbody>
  <tr>
    <th width="10%">City</th>
    <th>Population</th>
  </tr>
<?
    # then display the results...
    while($row = $result->fetch_object())
      printf(<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
              $row->Name, $row->Population);
?>
  </tbody
</table>
<?
  # ...and verify the number of rows that were retrieved
    printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's own Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

- Also remember that *each `NDB` table must have a primary key*. If no primary key is defined by the user when a table is created, the `NDB Cluster` storage engine will automatically generate a hidden one. (**Note**: This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created keys.)

17.3.6. Safe Shutdown and Restart

To shut down the cluster simply enter the following in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

This will cause the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. Note that the `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. See Section 4.3.1, "Using Options on the Command Line".

To restart the cluster, simply run these commands:

- On the management host (`192.168.0.10` in our setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (`192.168.0.30` and `192.168.0.40`):

  ```
  shell> ndbd
  ```

  Remember **not** to invoke this command with the `--initial` option when restarting an NDBD node normally.

- And on the SQL host (`192.168.0.20`):

  ```
  shell> mysqld &
  ```

For information on making Cluster backups, see Section 17.6.5.2, "Using The Management Server to Create a Backup".

To restore the cluster from backup requires the use of the `ndb_restore` command. This is covered in Section 17.6.5.3, "How to Restore a Cluster Backup".

More information on configuring MySQL Cluster can be found in Section 17.4, "MySQL Cluster Configuration".

17.4. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in only one respect from a normal (non-clustered) MySQL server, in that it employs the `NDB Cluster` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

In order to avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you will need to modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

Since the MySQL server is a part of the cluster, it will also need to know how to access an MGM node in order to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify its location elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

17.4.1. Building MySQL Cluster from Source Code

`NDB`, the Cluster storage engine, is available in binary distributions for Linux, Mac OS X, and Solar-

is. It is not yet supported on Windows, but we intend to make it available for win32 and other platforms in the near future.

If you choose to build from a source tarball or the MySQL 5.1 BitKeeper tree, be sure to use the `--with-ndbcluster` option when running `configure`. You can also use the `BUILD/compile-pentium-max` build script. Note that this script includes OpenSSL, so you must have or obtain OpenSSL to build successfully; otherwise you will need to modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, then perform the usual tests and installation procedure. See Section 2.8.3, “Installing from the Development Source Tree”.

17.4.2. Installing the Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See Chapter 2, *Installing MySQL*, if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

17.4.3. Quick Test Setup of MySQL Cluster

In order to familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` with the following information, substituting appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: DB, API, and MGM are aliases for NDBD, MYSQLD, and NDB_MGMD
# respectively. DB and API are deprecated and should not be used in new
# installations.
[NDBD DEFAULT]
NoOfReplicas= 1

[MYSQLD DEFAULT]
[NDB_MGMD DEFAULT]
[TCP DEFAULT]

[NDB_MGMD]
HostName= myhost.example.com

[NDBD]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[MYSQLD]
```

```
[MYSQLD]
[MYSQLD]
```

You can now start the management server as follows:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single DB node by running `ndbd`. When starting `ndbd` for a given DB node for the very first time, you should use the `--initial` option as shown here:

```
shell> ndbd --initial
```

For subsequent `ndbd` starts, you will generally **not** want to use the `--initial` option:

```
shell> ndbd
```

The reason for this is that the `--initial` option will delete all existing data and log files (as well as all table metadata) for this data node and create new ones. One exception to this rule is when re-starting the cluster and restoring from backup after adding new data nodes.

By default, `ndbd` will look for the management server at `localhost` on port 1186.

Note: If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, go to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.5-alpha-Max

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G

...
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
*************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

(Note that the row numbers shown in the example output above may be different from those shown on your system, depending upon the MySQL version being used and how it is configured.)

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.5-alpha-Max

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
       Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client as shown:

```
shell> ndb_mgm
```

You can then use the `SHOW` command from within the management client in order to obtain a report on the cluster's status:

```
NDB> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]     1 node(s)
id=2    @127.0.0.1  (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @127.0.0.1  (Version: 3.5.3)

[mysqld(API)]   3 node(s)
id=3    @127.0.0.1  (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

17.4.4. Configuration File

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file is read only by the MySQL Cluster management server, which then distributes the information contained in this file to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change which we have not documented, please use our Bugs Database [http://bugs.mysql.com/] to report it.

17.4.4.1. Example Configuration for a MySQL Cluster

In order to support MySQL Cluster, you will need to update `my.cnf` as shown in the example below. Note that the options shown here should not be confused with those occurring in `config.ini` files. You may also specify these parameters when invoking the executables from the command line.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see Section 17.4.4.2, “The MySQL Cluster `connectstring`”.)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` for settings to be read by and affecting all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Currently the configuration file is in INI format, and is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=[<path>]<filename>` on the command line with `ndb_mgmd`. If the configuration file is not specified, `ndb_mgmd` by default tries to read a `config.ini` file located in the current working directory.

Default values are defined for most parameters, and can also be specified in `config.ini`. To cre-

ate a default value section, simply add the word `DEFAULT` to the section name. For example, data nodes are configured using `[NDBD]` sections. If all data nodes use the same data memory size, and this is not the same as the default size, create an `[NDBD DEFAULT]` section containing a `DataMemory` line to specify the default data memory size for all data nodes.

The INI format consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard format is that the parameter name and value can be separated by a colon (‘`:`’) as well as the equals sign (‘`=`’); another is that sections are not uniquely identified by name. Instead, unique entries (such as two different nodes of the same type) are identified by a unique ID.

At a minimum, the configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown below:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the management
# server)
# The first MySQL Server can be started from any host. The second can be starte
# only on the host mysqld_5.mysql.com

[NDBD DEFAULT]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[NDB_MGMD]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[NDBD]
HostName= ndbd_2.mysql.com

[NDBD]
HostName= ndbd_3.mysql.com

[MYSQLD]
[MYSQLD]
HostName= mysqld_5.mysql.com
```

There are six different sections in this configuration file:

- `[COMPUTER]`: Defines the cluster hosts.
- `[NDBD]`: Defines the cluster's data nodes.
- `[MYSQLD]`: Defines the cluster's MySQL server nodes.
- `[MGM]` or `[NDB_MGMD]`: Defines the cluster's management server node.
- `[TCP]`: Defines TCP/IP connections between nodes in the cluster, with TCP/IP being the default connection protocol.
- `[SHM]`: Defines shared-memory connections between nodes. Formerly, this type of connection was available only in binaries that were built using the `--with-ndb-shm` option. In MySQL 5.1-Max, it is enabled by default, but should still be considered experimental.

Note that each node has its own section in the `config.ini`. For instance, since this cluster has two data nodes, the configuration file contains two sections defining these nodes.

You can define `DEFAULT` values for each section. All Cluster parameter names are case-insensitive.

17.4.4.2. The MySQL Cluster `connectstring`

With the exception of the MySQL Cluster management server (ndb_mgmd), each node making up a MySQL Cluster requires a *connectstring* which points to the management server's location. This is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
<connectstring> :=
    [<nodeid-specification>,]<host-specification>[,<host-specification>]

<nodeid-specification> := node_id

<host-specification> := host[:port]
```

node_id is an integer larger than 1 which identifies a node in config.ini. *port* is an integer referring to a regular Unix port. *host* is a string representing a valid Internet host address.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):   "myhost1"
```

All nodes will use localhost:1186 as the default connectstring value if none is provided. If <port> is omitted from the connectstring, the default port is 1186. This port should always be available on the network, since it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple <host-specification> values, it is possible to designate several redundant management servers. A cluster node will attempt to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connectstring:

- Each executable has its own command line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.
- For backward compatibility, two other options are available, using the same syntax:

  1. Set the NDB_CONNECTSTRING environment variable to contain the connectstring.
  2. Write the connectstring for each executable into a text file named Ndb.cfg and place this file in the executable's startup directory.

  However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the my.cnf file for each executable.

17.4.4.3. Defining the Computers Making up a MySQL Cluster

The [COMPUTER] section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- [COMPUTER]Id

  This is an integer value, used to refer to the host computer elsewhere in the configuration file.

- [COMPUTER]HostName

  This is the computer's hostname or IP address.

17.4.4.4. Defining the MySQL Cluster Management Server

The `[NDB_MGMD]` section (or its alias `[MGM]`) is used to configure the behavior of the management server. All parameters in the following list can be omitted and, if so, will assume their default values. **Note**: If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `[NDB_MGMD]Id`

  Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

- `[NDB_MGMD]ExecuteOnComputer`

  This refers to one of the computers defined in the `[COMPUTER]` section.

- `[NDB_MGMD]PortNumber`

  This is the port number on which the management server listens for configuration requests and management commands.

- `[NDB_MGMD]LogDestination`

  This parameter specifies where to send cluster logging information. There are three options in this regard: `CONSOLE`, `SYSLOG`, and `FILE`:

  - `CONSOLE` outputs the log to `stdout`:

    ```
    CONSOLE
    ```

  - `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

    Note: Not every facility is necessarily supported by every operating system.

    ```
    SYSLOG:facility=syslog
    ```

  - `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

    - `filename`: The name of the logfile.
    - `maxsize`: The maximum size to which the file can grow before logging rolls over to a new file. When this occurs, the old logfile is renamed by appending `.x` to the filename, where `x` is the next number not yet used with this name.
    - `maxfiles`: The maximum number of logfiles.

    ```
    FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
    ```

    It is possible to specify multiple log destinations as shown here, using a semicolon-delimited string:

    ```
    CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
    ```

    The default value for the `FILE` parameter is `_cluster.log,maxsize=1000000,maxfiles FILE:filename=ndb_`*`node_id`*`=6`, where `node_id` is the ID of the node.

- `[NDB_MGMD]ArbitrationRank`

  This parameter is used to define which nodes can act as arbitrators. Only MGM nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

  - `0`: The node will never be used as an arbitrator.
  - `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
  - `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

  Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

- `[NDB_MGMD]ArbitrationDelay`

  An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `[NDB_MGMD]DataDir`

  This sets the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's pid file. (For log files, this can be overridden by setting the `FILE` parameter for `[NDB_MGMD]LogDestination` as discussed previously in this section.)

17.4.4.5. Defining MySQL Cluster Data Nodes

The `[NDBD]` section is used to configure the behavior of the cluster's data nodes. There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`.
- The parameter `NoOfReplicas`

These need to be defined in the `[NDBD DEFAULT]` section.

Most data node parameters are set in the `[NDBD DEFAULT]` section. Only those parameters explicitly stated as being able to set local values are allowed to be changed in the `[NDBD]` section. `HostName`, `Id` and `ExecuteOnComputer` *must* be defined in the local `[NDBD]` section.

Identifying Data Nodes

The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

For each parameter it is possible to use `k`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100k` means 100 × 1024 = 102400.) Parameters and values are currently case-sensitive.

- `[NBDB]Id`

  This is the node ID used as the address of the node for all cluster internal messages. This is an integer between 1 and 63. Each node in the cluster has a unique identity.

- `[NDBD]ExecuteOnComputer`

This refers to one of the computers (hosts) defined in the `COMPUTER` section.

- `[NDBD]HostName`

  Specifying this parameter has an effect similar to specifying `ExecuteOnComputer`. It defines the hostname of the computer the storage node on which is to reside. Either this parameter or `ExecuteOnComputer` is required in order to specify a hostname other than `localhost`.

- (*OBSOLETE*) `[NDBD]ServerPort`

  Each node in the cluster uses a port to connect to other nodes. This port is used also for non-TCP transporters in the connection setup phase. Since, the default port is allocated dynamically in such a way as to ensure that no two nodes on the same computer receive the same port number, it should not normally be necessary to specify a value for this parameter.

- `[NDBD]NoOfReplicas`

  This global parameter can be set only in the `[NDBD DEFAULT]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

  Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer, as in this situation a single hardware failure would cause the entire cluster to crash.

  If no node IDs are provided then the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

  There is no default value for `NoOfReplicas`; the maximum possible value is 4.

- `[NDBD]DataDir`

  This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

- `[NDBD]FileSystemPath`

  This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs and data files are placed. The default is the directory specified by `DataDir`. **Note**: This directory must exist before the `ndbd` process is initiated.

  The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's filesystem is created. This subdirectory contains the node ID. For example, if the node ID is 2, then this subdirectory is named `ndb_2_fs`.

- `[NDBD]BackupDataDir`

  It is also possible to specify the directory in which backups are placed. By default, this directory is *`FileSystemPath/`*`BACKUP`. (See above.)

Data Memory and Index Memory

`DataMemory` and `IndexMemory` are parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated in order to reflect actual usage by the cluster:

- `[NDBD]DataMemory`

  This parameter defines the amount of space available for storing database records. The entire amount is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate this value.

  The memory allocated by `DataMemory` is used to store both the actual records and indexes. Each record is currently of fixed size. (Even `VARCHAR` columns are stored as fixed-width columns.) There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page. The maximum record size is currently 8052 bytes.

  The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d` *`db_name table_name`* in the management client.

  The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`. Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. Performing a node recovery also will compress the partition because all records are inserted into empty partitions from other live nodes.

  The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

  - Large transactions are not any faster than smaller ones
  - Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
  - Large transactions use more memory

  The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2-4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason. In addition, it is also possible to run more than one `ndbd` process per machine, and this may prove advantageous on machines with multiple CPUs.

- `[NDBD]IndexMemory`

  This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

  The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary

keys larger than 32 bytes another 8 bytes is added.

Consider a table defined by

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

There are 12 bytes overhead (having no nullable columns saves 4 bytes of overhead) plus 12 bytes of data per record. In addition we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This table will consume an additional 29 bytes of index memory per record in the `example` table as well as 12 bytes of overhead, plus 8 bytes of record data.

Thus, for one million records, we need 58 MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64 MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with 2 replicas, then there will be two node groups. Thus, the total data memory available is 2*`DataMemory` for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Since data is distributed evenly over all nodes in the cluster the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

Transaction Parameters

The next three parameters which we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node; `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems us-

ing small transactions, in order to ensure that these do not use excessive memory.

- `[NDBD]MaxNoOfConcurrentTransactions`

  For each active transaction in the cluster there must be a record in one of the cluster nodes. The task of coordinating transactions is spread among the nodes: the total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

  Transaction records are allocated to individual MySQL servers. Normally there is at least one transaction record allocated per connection that using any table in the cluster. For this reason, one should ensure that there are more transaction records in the cluster than there are concurrent connections to all MySQL servers in the cluster.

  This parameter must be set to the same value for all cluster nodes.

  Changing this parameter is never safe and doing so can cause a cluster to crash. When a node crashes one of the nodes (actually the oldest surviving node) will build up the transaction state of all transactions ongoing in the crashed node at the time of the crash. It is thus important that this node has as many transaction records as the failed node.

  The default value for this parameter is 4096.

- `[NDBD]MaxNoOfConcurrentOperations`

  It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

  Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed in order to find UNDO records for rollback, lock queues, and other purposes.

  This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has 4 data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000.

  Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

  When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

  The default value for this parameter is 32768.

  This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

  A very large transaction performed on an 8-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all 8 nodes. Thus, if it is necessary to configure the system for one very large transaction, then it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

  It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `[NDBD]MaxNoOfLocalOperations`

  By default, this parameter is calculated as 1.1 * `MaxNoOfConcurrentOperations` which fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, then it is a good idea to override the default value by explicitly specifying this parameter.

Transaction Temporary Storage

The next set of parameters is used to determine temporary storage when executing a query which is part of a Cluster transaction. All records are released when the query is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these to enable better parallelism in the system, while users whose applications require relatively small transactions can decrease the values in order to save memory.

- `[NDBD]MaxNoOfConcurrentIndexOperations`

  For queries using a unique hash index another, temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus this record is only allocated while executing a part of a query, as soon as this part has been executed the record is released. The state needed to handle aborts and commits is handled by the normal operation records where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

  The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree parallelism is not required for the cluster.

- `[NDBD]MaxNoOfFiredTriggers`

  The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

  A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `[NDBD]TransactionBufferMemory`

  The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

  Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000*128 bytes (500KB). A similar buffer for key info, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module which handles transaction coordination.

Scans and Buffering

There are additional parameters in the `Dblqh` module (in `ndb/`

src/kernel/blocks/Dblqh/Dblqh.hpp) which affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000*128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

The default value for TransactionBufferMemory is 1MB.

- [NDBD]MaxNoOfConcurrentScans

  This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

  Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. Since the order is kept on the local partitions only, it is necessary to perform the index scan on all partitions.

  The default value of MaxNoOfConcurrentScans is 256. The maximum value is 500.

  This parameter specifies the number of scans possible in the transaction coordinator. If the number of local scan records is not provided, it is calculated as the product of MaxNoOfConcurrentScans and the number of data nodes in the system.

- [NDBD]MaxNoOfLocalScans

  Specifies the number of local scan records if many scans are not fully parallelized.

- [NDBD]BatchSizePerLocalScan

  This parameter is used to calculate the number of lock records which needs to be there to handle many concurrent scan operations.

  The default value is 64; this value has a strong connection to the ScanBatchSize defined in the SQL nodes.

- [NDBD]LongMessageBuffer

  This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. By default it is set to 1MB.

Logging and Checkpointing

- [NDBD]NoOfFragmentLogFiles

  This parameter sets the size of the node's REDO log files. REDO log files are organized in a ring. It is extremely important that the first and last log files (sometimes referred to as the “head” and “tail” log files, respectively) do not meet; when these approach one another too closely, the node will begin aborting all transactions encompassing updates due to a lack of room for new log records.

  A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 8, which means 8 sets of 4 16MB files for a total of 512MB. In other words, REDO log space must be allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher in order to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, then all updating transactions will be aborted with internal error code 410, or `Out of log file space temporarily`. This condition will prevail until a checkpoint has completed and the log tail can be moved forward.

- `[NDBD]MaxNoOfSavedMessages`

  This parameter sets the maximum number of trace files that will be kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

  The default is 25 trace files.

Metadata Objects

The next set of parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as "suggestions" to the cluster, and any that are not specified revert to the default values shown.

- `[NDBD]MaxNoOfAttributes`

  Defines the number of attributes that can be defined in the cluster.

  The default value for this parameter is 1000, with the minimum possible value being 32. There is no maximum. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

  When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` commands that you might wish to perform in future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used. For example, if a table requires 100 attributes, and you wish to be able to alter it later, then you need to set the value of `MaxNoOfAttributes` to 300. A good rule of thumb is that, if you can create all desired tables without any problems, then add 2 times the number of attributes in the largest table to `MaxNoOfAttributes` to be sure. You should also verify that this number is sufficient by trying an actual `ALTER TABLE` after doing so. If this is not successful, increase `MaxNoOfAttributes` by another multiple of the original value and test it again.

- `[NDBD]MaxNoOfTables`

  A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

  For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

  The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `[NDBD]MaxNoOfOrderedIndexes`

  For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- `[NDBD]MaxNoOfUniqueHashIndexes`

  For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default there an ordered index is also defined for each unique index. To prevent this, you must use the `USING HASH` option when defining the unique index.

  The default value is 64. Each index consumes approximately 15KB per node.

- `[NDBD]MaxNoOfTriggers`

  Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that 3 triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

  Note: When replication between clusters is supported, this will also make use of internal triggers.

  This parameter sets the maximum number of trigger objects in the cluster.

  The default value for this parameter is 768.

- `[NDBD]MaxNoOfIndexes`

  This parameter is deprecated in MySQL 5.1; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

  This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

  The default value of this parameter is 128.

Boolean Parameters

The behavior of data nodes is also affected by a set of parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `[NDBD]LockPagesInMainMemory`

  For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

  By default, this feature is disabled.

- `[NDBD]StopOnError`

  This parameter specifies whether an NDBD process is to exit or to perform an automatic restart when an error condition is encountered.

  This feature is enabled by default.

- `[NDBD]Diskless`

  It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables will be

preserved after a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important: This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, backups are performed but backup data is not actually stored.

This feature is enabled by setting `Diskless` to either `1` or `Y`. `Diskless` is disabled by default.

- `[NDBD]RestartOnErrorInsert`

  This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

  By default, this feature is disabled.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this will be mentioned where applicable below.

- `[NDBD]TimeBetweenWatchDogCheck`

  To prevent the main thread from getting stuck in an endless loop at some point, a "watchdog" thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, it is terminated by the watchdog thread.

  This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

  The default timeout is 4000 milliseconds (4 seconds).

- `[NDBD]StartPartialTimeout`

  This parameter specifies the time that the cluster will wait for all storage nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

  The default value is 30000 milliseconds (30 seconds). `0` means eternal time out; in other words, the cluster may start only if all nodes are available.

- `[NDBD]StartPartitionedTimeout`

  If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed.

  The default timeout is 60000 milliseconds (60 seconds).

- `[NDBD]StartFailureTimeout`

  If a data node has not completed its startup sequence within the time specified by this parameter, then the node startup will fail. Setting this parameter to `0` means that no data node timeout is applied.

  The default value is 60000 milliseconds (60 seconds). For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a storage node containing several gigabytes of data, a period as long as 10-15 minutes (that is, 600,000 to 1,000,000 milliseconds) might be required in order to to perform a node restart.

- `[NDBD]HeartbeatIntervalDbDb`

  One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

  The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds then obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade but only in small increments.

- `[NDBD]HeartbeatIntervalDbApi`

  Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead”, in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

  The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each storage node watches the MySQL servers connected to it, independently of all other data nodes.

- `[NDBD]TimeBetweenLocalCheckpoints`

  This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

  The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

  All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `[NDBD]TimeBetweenGlobalCheckpoints`

  When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

  It is also important to ensure that even the worst of cases — a complete crash of the cluster — is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group; later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

  This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `[NDBD]TimeBetweenInactiveTransactionAbortCheck`

  Time-out handling is performed by checking a timer on each transaction once for every interval

specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, then every transaction will be checked for timing out once per second.

The default value for this parameter is 1000 milliseconds (1 second).

- `[NDBD]TransactionInactiveTimeout`

  If the transaction is currently not performing any queries but is waiting for further user input, this parameter states the maximum time that the user can wait before the transaction is aborted.

  The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long a time this parameter should be set to a much smaller value. The unit is milliseconds.

- `[NDBD]TransactionDeadlockDetectionTimeout`

  When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

  1. The node is “dead”

  2. The operation has entered a lock queue

  3. The node requested to perform the action could be heavily overloaded.

  This timeout parameter states how long the transaction coordinator will wait for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. Setting it too high can cause a undesirable behavior in situations involving deadlocks and node failure.

  The default timeout value is 1200 milliseconds (1.2 seconds).

- `[NDBD]NoOfDiskPagesToDiskAfterRestartTUP`

  When executing a local checkpoint the algorithm flushes all data pages to disk. Merely doing as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB; thus, this parameter is specified in units of 80KB per second. Therefore, setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of `20` entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages; that is, this parameter handles the limitation of writes from data memory. UNDO log records for index pages are handled by the parameter `NoOfDiskPagesToDiskAfterRestartACC`. (See the entry for `IndexMemory` for information about index pages.)

  In short, this parameter specifies how quickly local checkpoints will be executed, and operates in conjunction with `NoOfFragmentLogFiles`, `DataMemory`, and `IndexMemory`.

  The default value is 40 (3.2MB of data pages per second).

- `[NDBD]NoOfDiskPagesToDiskAfterRestartACC`

  This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

  The default value of this parameter is 20 index memory pages per second (1.6MB per second).

- `[NDBD]NoOfDiskPagesToDiskDuringRestartTUP`

  This parameter in a similar fashion as `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local check-

points executed in the node when a node is restarting. As part of all node restarts a local checkpoint is always performed. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

- `[NDBD]NoOfDiskPagesToDiskDuringRestartACC`

  Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

  As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

  The default value is 20 (1.6MB per second).

- `[NDBD]ArbitrationTimeout`

  This parameter specifies the time that the data node will wait for a response from the arbitrator to an arbitration message. If this is exceeded, then it is assumed that the network has split.

  The default value is 1000 milliseconds (1 second).

Buffering and Logging

Several configuration parameters corresponding to former compile-time parameters are also available. These enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, then these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the `NDB` storage engine's filesystem abstraction layer.

- `[NDBD]UndoIndexBuffer`

  This buffer is used during local checkpoints. The `NDB` storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. In order to produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

  The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

  Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to insure that these operations need no UNDO logging.

  This buffer is 2MB by default. The minimum value is 1MB, and for most applications the minimum is sufficient. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 `Index UNDO buffers overloaded`.

- `[NDBD]UndoDataBuffer`

  The UNDO data buffer plays the same role as the UNDO index buffer, except that it is used with

regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Since UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

For some applications this amount of memory may be unnecessarily large. In such cases it is possible to decrease this size down to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, then it is a good idea to check if the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 `Data UNDO buffers overloaded`.

- `[NDBD]RedoBuffer`

  All update activities also need to be logged. This log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a "fuzzy" checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

  This buffer is 8MB by default. The minimum value is 1MB.

  If this buffer is too small, the NDB storage engine issues error code 1221 `REDO log buffers overloaded`.

In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. There are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `[NDBD]LogLevelStartup`

  Reporting level for events generated during startup of the process.

  The default level is 1.

- `[NDBD]LogLevelShutdown`

  Reporting level for events generated as part of graceful shutdown of a node.

  The default level is 0.

- `[NDBD]LogLevelStatistic`

  Reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

  The default level is 0.

- `[NDBD]LogLevelCheckpoint`

Reporting level for events generated by local and global checkpoints.

The default level is 0.

- `[NDBD]LogLevelNodeRestart`

  Reporting level for events generated during node restart.

  The default level is 0.

- `[NDBD]LogLevelConnection`

  Reporting level for events generated by connections between cluster nodes.

  The default level is 0.

- `[NDBD]LogLevelError`

  Reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

  The default level is 0.

- `[NDBD]LogLevelInfo`

  Reporting level for events generated for information about the general state of the cluster.

  The default level is 0.

Backup Parameters

The parameters discussed in this section define memory buffers set aside for execution of online backups.

- `[NDBD]BackupDataBufferSize`

  In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize` (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed and have thus freed up memory so that scanning may continue.

  The default value for this parameter is 2MB.

- `[NDBD]BackupLogBufferSize`

  The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the back up logbuffer must be big enough to handle the load caused by write activities while the backup is being made.

  The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster will be likely to be able to perform the desired operations.

  It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- `[NDBD]BackupMemory`

  This parameter is simply the sum of `BackupDataBufferSize` and `BackupLogBuffer-Size`.

  The default value is 2MB + 2MB = 4MB.

- `[NDBD]BackupWriteSize`

  This parameter specifies the size of messages written to disk by the backup log and backup data buffers.

  The default value is 32KB.

17.4.4.6. Defining the SQL Nodes in a MySQL Cluster

The `[MYSQLD]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, then any host can use this SQL node.

- `[MYSQLD]Id`

  This value is used as the address of the node by all cluster internal messages, and must be an integer between 1 and 63. Each cluster node must have a unique identity within the cluster.

- `[MYSQLD]ExecuteOnComputer`

  This refers to one of the computers (hosts) defined in a `[COMPUTER]` section of the configuration file.

- `[MYSQLD]ArbitrationRank`

  This parameter is used to define which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of `0` means that the given node will never be used as an arbitrator, a value of `1` gives the node high priority as an arbitrator, and a value of `2` gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to `1` (the default) and those for all SQL nodes to `0`.

- `[MYSQLD]ArbitrationDelay`

  Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `[MYSQLD]BatchByteSize`

  For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size will be limited by both parameters.

  The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

  This parameter is measured in bytes and by default is equal to 32KB.

- `[MYSQLD]BatchSize`

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- `[MYSQLD]MaxScanBatchSize`

  The batch size is the size of each batch sent from each data node. Most scans are performed in parallel in order to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

  The default value of this parameter is set to 256KB. Its maximum size is 16MB.

17.4.4.7. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for establishing connections in MySQL Cluster. It is normally not necessary to define connections because Cluster automatically set ups a connection between each of the data nodes, between each data node and all MySQL server nodes, and between each data node and the management server. (For one exception to this rule, see Section 17.4.4.8, “MySQL Cluster TCP/IP Connections Using Direct Connections”.)

It is only necessary to define a connection in order to override the default connection parameters. In that case it is necessary to define at least *`NodeId1`*, *`NodeId2`*, and the parameters to change.

It is also possible to change the default values for these parameters by setting them in the `[TCP DEFAULT]` section.

- `[TCP]`*`NodeId1`*, `[TCP]`*`NodeId2`*

  To identify a connection between two nodes it is necessary to provide the node identities for both of them in the `[TCP]` section of the configuration file.

- `[TCP]SendBufferMemory`

  TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer. The default size of the send buffer is 256KB.

- `[TCP]SendSignalId`

  In order to be able to retrace a distributed message diagram it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default.

- `[TCP]Checksum`

  This parameter is also a boolean (`Y`/`N` or `1`/`0`) parameter, and is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature insures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `[TCP]PortNumber`

  (**OBSOLETE**.) This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

- `[TCP]ReceiveBufferMemory`

  Specifies the size of the buffer used when receiving data from the TCP/IP socket. There is seldom any need to change this parameter from its default value of 64KB, except possibly in order to save memory.

17.4.4.8. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[TCP]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least 4 hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[NDB_MGMD]
Id=1
HostName=172.23.72.20

# SQL Node
[MYSQLD]
Id=2
HostName=172.23.72.21

# Data Nodes
[NDBD]
Id=3
HostName=172.23.72.22

[NDBD]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[TCP]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that in order to take the best advantage of direct connections in this fashion with more than 2 data nodes, you will need to have a direct connection between each data node and every other data node in the same node group.

17.4.4.9. MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible, chiefly where more than one node runs concurrently on the same cluster host. (In very early versions of MySQL Cluster, shared memory segments functioned only when the `-max` binary was built using `--with-ndb-shm`.) When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have default values that should work well in most cases.

Important: *SHM functionality is considered experimental only*. It is not officially supported in any MySQL release series up to and including 5.1. This means that you must determine for yourself or by using our free resources (forums, mailing lists) whether it can be made to work correctly in your specific case.

- `[SHM]NodeId1`, `[SHM]NodeId2`

  To identify a connection between two nodes it is necessary to provide node identifiers for each

of them, as `NodeId1` and `NodeId2`.

- `[SHM]ShmKey`

  When setting up shared memory segments, a node ID is used to identify uniquely the shared memory segment to use for the communication. This is expressed as an integer which does not have a default value.

- `[SHM]ShmSize`

  Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- `[SHM]SendSignalId`

  In order to retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default.

- `[SHM]Checksum`

  This parameter is also a `Y`/`N` parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

  This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

17.4.4.10. MySQL Cluster SCI Transport Connections

Using SCI transporters to connect nodes in a MySQL Cluster is supported only when the MySQL-Max binaries are built using `--with-ndb-sci=`*`/your/path/to/SCI`*. The *`path`* should point to a directory that contains at a minimum `lib` and `include` directories containing SISCI libraries and header files.

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least 2 CPUs dedicated for use by `ndbd` processes. There should be at least 1 CPU per `ndbd` process, with at least 1 CPU left in reserve to handle operating system activities.

- `[SCI]NodeId1`, `[SCI]NodeId2`

  To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `[SCI]Host1SciId0`

  This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `[SCI]Host1SciId1`

  It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `[SCI]Host2SciId0`

  This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `[SCI]Host2SciId1`

  When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `[SCI]SharedBufferSize`

  Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1 MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `[SCI]SendLimit`

  A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default this is set to 8kB. Our benchmarks show that performance is best at 64 kB but 16kB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8kB.

- `[SCI]SendSignalId`

  In order to trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default.

- `[SCI]Checksum`

  This parameter is also a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

17.5. Process Management in MySQL Cluster

Understanding how to manage MySQL Cluster requires a knowledge of four essential processes. In the next few sections of this chapter, we cover the roles played by these processes in a cluster, how to use them, and what startup options are available for each of them.

17.5.1. MySQL Server Process Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDB Cluster` storage engine, as it is in the precompiled `-max` binaries available from http://dev.mysql.com/downloads/.

If the `mysqld` binary has been built in such a manner, the `NDB Cluster` storage engine is still disabled by default. You can use either of two possible options for enabling the `NDB Cluster` storage engine:

Use `--ndbcluster` as a startup option when starting `mysqld`

- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDB Cluster` storage engine enabled is to issue the command `SHOW ENGINES` in the MySQL Monitor (`mysql`). You should see the value `YES` in the row listing `NDBCLUSTER`; if you see `NO` in this row (or if there is no such row displayed in the output), you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, then you need to enable it in either one of the two ways shown above.

In order to read cluster configuration data, the MySQL server requires at a minimum 3 pieces of information:

- The MySQL server's own cluster node ID.
- The hostname or IP address for the management server (MGM node).
- The port on which it can connect to the management server.

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the hostname or IP address as well as the port where the management server can be found.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 17.4.4.2, "The MySQL Cluster `connectstring`", for more info on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We sometimes refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to access node data for reading and updating.

17.5.2. ndbd, the Storage Engine Node Process

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process empowers a storage node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes co-operate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the configuration file. These log files are listed below. Note that *`node_id`* represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the storage node whose node ID is **2**.

- `ndb_`*`node_id`*`_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

  ```
  Date/Time: Saturday 30 July 2004 - 00:20:01
  Type of error: error
  Message: Internal program error (failed ndbrequire)
  Fault ID: 2341
  Problem data: DbtupFixAlloc.cpp
  Object of reference: DBTUP (Line: 173)
  ProgramName: NDB Kernel
  ProcessID: 14909
  TraceFile: ndb_2_trace.log.2
  ***EOM***
  ```

  Note: *It is very important to be aware that the last entry in the error log file is not necessarily*

the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_*node_id*_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- ndb_*node_id*_trace.log.*trace_id* is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

  It is possible to configure the number of these trace files that will be created before old files are overwritten. *trace_id* is a number which is incremented for each successive trace file.

- ndb_*node_id*_trace.log.next is the file that keeps track of the next trace file number to be assigned.

- ndb_*node_id*_out.log is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon.

- ndb_*node_id*.pid is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- ndb_*node_id*_signal.log is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the pid-file remains in effect even after the process has terminated.

When starting ndbd it may also be necessary to specify the hostname of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 17.4.4.2, “The MySQL Cluster connectstring”, for additional information about this issue.

When ndbd starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the ndbd process if it is configured to do so. Thus, if you attempt to kill ndbd via the Unix kill command, it is necessary to kill both processes. A more proper way to terminate an ndbd process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent activites. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the ndbd process. In a system performing a large number of operations, including updates, the ndbd process can consume up to 2 CPUs if permitted to do so. For a machine with many CPUs it is recommended to use several ndbd processes which belong to different node groups.

17.5.3. ndb_mgmd, the Management Server Process

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the DataDir as specified in the configuration file. In the list that follows, *node_id* is the unique node identifier.

- config.ini is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Setting up this file is discussed in Section 17.4, "MySQL Cluster Configuration".
- ndb_*node_id*_cluster.log is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 17.6, "Management of MySQL Cluster".

  When the size of the cluster log reaches one million bytes, the file is renamed to ndb_*node_id*_cluster.log.*seq_id*, where *seq_id* is the sequence number of the cluster log file. (For example: If 1, 2, and 3 already exist, the next log file will be named using the number 4.)
- ndb_*node_id*_out.log is the file used for stdout and stderr when running the management server as a daemon.
- ndb_*node_id*.pid is the PID file used when running the management server as a daemon.

17.5.4. ndb_mgm, the Management Client Process

The management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client access the management server using a C API that advanced users can also employ for programming dedicated management processes which can perform tasks similar to those performed by ndb_mgm.

When starting the management client, it is necessary to supply the hostname and port of the management server as in the example below. The default values are localhost and 1186.

```
shell> ndb_mgm localhost 1186
```

Additional information about using ndb_mgm can be found in Section 17.5.5.4, "Command Options for ndb_mgm", and Section 17.6.2, "Commands in the Management Client".

17.5.5. Command Options for MySQL Cluster Processes

All MySQL Cluster executables (except for mysqld) take the following options. Users of earlier MySQL Cluster versions should note that some of these switches have been changed from those in MySQL 4.1 Cluster in order to make them consistent with one another as well as with mysqld. You can use the -? switch to view a list of supported options.

- --help --usage, -?

  Prints a short list with descriptions of the available command options.
- --connect-string=*connect_string*, -c *connect_string*

  connect_string sets the connect string to the management server as a command option.

  ```
  shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
  ```

- `--debug[=options]`

  This option can only be used for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--execute=command -e command`

  Can be used to send a command to a Cluster executable from the system shell. For example, either of the following:

  ```
  shell> ndb_mgm -e show
  ```

  or

  ```
  shell> ndb_mgm --execute="SHOW"
  ```

  is equivalent to

  ```
  NDB> SHOW;
  ```

  This is analogous to how the `-e` option works with the `mysql` command-line client. See Section 4.3.1, “Using Options on the Command Line”.

- `--version, -V`

  Prints the version number of the `ndbd` process. The version number is the MySQL Cluster version number. The version number is relevant because not all versions can be used together, and at startup the MySQL Cluster processes verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online software upgrade of MySQL Cluster (see `Software Upgrade of MySQL Cluster`).

17.5.5.1. MySQL Cluster-Related Command Options for `mysqld`

- `--ndb-connectstring=connect_string`

  When using the `NDB` storage engine, it is possible through setting this option to specify the management server that distributes cluster configuration data.

- `--ndbcluster`

  If the binary includes support for the `NDB Cluster` storage engine, the default disabling of the `NDB Cluster` storage engine (also referred to more simply as the `NDB` storage engine) can be overridden by using this option. The `NDB Cluster` storage engine is necessary for using MySQL Cluster.

- `--skip-ndbcluster`

  Disables the `NDB Cluster` storage engine. This option is activated by default for binaries where it is included; in other words, the `NDB Cluster` storage engine is disabled until activated via `--ndbcluster`. This option applies only if the server was compiled with support for the `NDB Cluster` storage engine.

17.5.5.2. Command Options for ndbd

For some common options see Section 17.5.5, “Command Options for MySQL Cluster Processes”.

- `--daemon, -d`

Instructs ndbd to execute as a daemon process (the default behavior). --nodaemon can be used to not start the process as a daemon.

- --initial

  Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

  An --initial start is to be used only the very first time that the ndbd process is started, as it removes all files from the Cluster filesystem and re-creates all REDO log files. The exceptions to this rule are:

  - When performing a software upgrade which has changed the contents of any files.
  - When restarting the node with a new version of ndbd.
  - As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case be aware that this node can no longer be used to restore data due to the destruction of the datafiles.

  This option does not affect any backup files that have already been created by the affected node.

- --nodaemon

  Instructs ndbd not to start as a daemon process. Useful when ndbd is being debugged and you want output to be redirected to the screen.

- --nostart

  Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it will not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper command to the management client.

17.5.5.3. Command Options for ndb_mgmd

For some common options see Section 17.5.5, “Command Options for MySQL Cluster Processes”.

- --config-file=*file_name*, -f *file_name*,

  Instructs the management server as to which file it should use for its configuration file. This option must be specified. The file name defaults to config.ini.

  Note: This option also can be given as -c file_name, but this shortcut is obsolete and should *not* be used in new installations.

- --daemon, -d

  Instructs ndb_mgmd to start as a daemon. This is the default behavior.

- --nodaemon

  Instructs the management server not to start as a daemon.

17.5.5.4. Command Options for ndb_mgm

For some common options see Section 17.5.5, “Command Options for MySQL Cluster Processes”.

- `[host_name [port_num]]`

  To start the management client it is necessary to specify where the management server resides, which means specifying the hostname and the port. The default hostname is `localhost`; the default port is 1186.

- `--try-reconnect=number`

  If the connection to the management server is broken, then the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *`number`* before giving up and reporting an error instead.

17.6. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in Section 17.4, “MySQL Cluster Configuration”, and Section 17.5, “Process Management in MySQL Cluster”.

The following sections cover the management of a running MySQL Cluster.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_`*`node_id`*`_cluster.log` in the management server's `DataDir` directory. (Recall that *`node_id`* represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

17.6.1. MySQL Cluster Startup Phases

This section describes the steps involved when the cluster is started.

There are several different startup types and modes, as shown here:

- **Initial Start**: The cluster starts with a clean filesystem on all data nodes. This occurs either when the cluster started for the very first time, or when it is restarted using the `--initial` option.
- **System Restart**: The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster resume operations from the point where it left off.
- **Node Restart**: This is the online restart of a cluster node while the cluster itself is running.
- **Initial Node Restart**: This is the same as a node restart, except that the node is reinitialized and started with a clean filesystem.

Prior to startup, each data node (`ndbd` process) must be initialized. This consists of the following:

1. Obtain a Node ID.
2. Fetch configuration data.
3. Allocate ports to be used for inter-node communications.
4. Allocate memory according to settings obtained from the configuration file.

Once each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Stage 0**

  Clear the cluster filesystem. This occurs *only* if the cluster was started with the `--initial` option.

- **Stage 1**

  Cluster connections are set up; inter-node communications are established. Cluster heartbeats are started.

- **Stage 2**

  The arbitrator node is elected.

  If this is a system restart, then the cluster determines the latest restorable global checkpoint.

- **Stage 3**

  This stage consists of the initialization of a number of internal cluster variables.

- **Stage 4**

  For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

  For a system restart:

  - Read schema or schemas.
  - Read data from the local checkpoint and undo logs.
  - Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.

- **Stage 5**

  If this is an initial start, create the `SYSTAB_0` and `NDB$EVENTS` internal system tables.

  For a node restart or an initial node restart:

  - The node is included in transaction handling operations.
  - The node's schema is compared with the master' and synchronized with it.
  - Synchronize data received in the form of `INSERT` from the other data nodes in this node's node group.
  - In all cases, wait for complete local checkpoint as determined by the arbitrator.

- **Stage 6**

  Update internal variables.

- **Stage 7**

  Update internal variables.

- **Stage 8**

  In a system restart, rebuild all indexes.

- **Stage 9**

  Update internal variables.

- **Stage 10**

  At this point in a node restart or initial node restart, APIs may connect to the node and being to receive events.

- **Stage 11**

  At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers.

Once this process is completed for an initial start or system restart, handling of transactions is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

17.6.2. Commands in the Management Client

In addition to the central configuration file, a cluster may also be controlled through a command line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

The management client has the following basic commands. In the listing that follows, *`node_id`* denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`

  Displays information on all available commands.

- `SHOW`

  Displays information on the cluster's status.

  Note: In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.

- *`node_id`* `START`

  Starts the data node identified by *`node_id`* (or all data nodes).

- *`node_id`* `STOP`

  Stops the data node identified by *`node_id`* (or all data nodes).

- *`node_id`* `RESTART [-N] [-I]`

  Restarts the data node identified by *`node_id`* (or all data nodes).

- *`node_id`* `STATUS`

  Displays status information for the data node identified by *`node_id`* (or for all data nodes).

- `ENTER SINGLE USER MODE` *`node_id`*

  Enters single-user mode, whereby only the MySQL server identified by the node ID *`node_id`* is allowed to access the database.

- `EXIT SINGLE USER MODE`

Exists single user mode allowing all SQL nodes (that is, all running `mysqld` processes) to access the database.

- `QUIT`

  Terminates the management client.

- `SHUTDOWN`

  Shuts down all cluster nodes, except for SQL nodes, and exits.

Commands for the event logs are given in the next section; commands for creating backups and restoring from backup are provided in a separate section on these topics.

17.6.3. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log. These are the **cluster log**, which includes events generated by all cluster nodes, and **node logs**, which are local to each data node.

Output generated by cluster event logging can have multiple destinations including a file, the management server console window, or `syslog`. Output generated by node event logging is written to the data node's console window.

Both sorts of event logs can be set to log different subsets of events.

Note: The cluster log is the log recommended for most uses, since it provides logging information for an entire cluster in a single file. Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important”.
- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

17.6.3.1. Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`

  Turn cluster log on.

- `CLUSTERLOG OFF`

  Turn cluster log off.

- `CLUSTERLOG INFO`

Information about cluster log settings.

- *node_id* CLUSTERLOG *category=threshold*

  Logs *category* events with priority less than or equal to *threshold* in the cluster log.

- CLUSTERLOG FILTER *severity_level*

  Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, then it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is changed to 3 or lower. Only events with priority 3 or lower are sent if the threshold is 3.

Event severity levels are shown below. (**Note**: These correspond to Unix syslog levels, except for LOG_EMERG and LOG_NOTICE, which are not used or mapped.)

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for NDB Cluster development

Event severity levels can be turned on or off. If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

17.6.3.2. Log Events

An event report as reported in the event logs has the following format: *datetime* [*string*]

severity -- message. For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

All reportable events are discussed in this section, ordered by category and severity level within each category.

`CONNECTION` Events

These are events associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
DB nodes connected	8	INFO	Data nodes connected
DB nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

`CHECKPOINT` Events

The logging messages shown below are associated with checkpoints.

(**Note**: GCP = Global Checkpoint, LCP = Local Checkpoint.)

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk
Report undo log blocked	7	INFO	UNDO logging blocked; buffer near overflow

`STARTUP` Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STTORRY	15	INFO	Blocks received after completion of restart
Undo records executed	15	INFO	
New REDO log started	10	INFO	GCI keep *X*, newest restorable GCI *Y*
New log started	10	INFO	Log part *X*, start MB *Y*, stop MB *Z*
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
DB node neighbors	8	INFO	Shows neighboring data nodes

DB node start phase *X* completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
DB node start phases initiated	1	INFO	NDB Cluster nodes starting
DB node all start phases completed	1	INFO	NDB Cluster nodes started
DB node shutdown initiated	1	INFO	Shutdown of data node has commenced
DB node shutdown aborted	1	INFO	Unable to shut down data node normally

`NODERESTART` Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was *X*	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are 8 different possible results for arbitration attempts: • Arbitration check failed - less than 1/2 nodes left • Arbitration check succeeded - node group majority • Arbitration check failed - missing node group • Network partitioning - arbitration required • Arbitration succeeded - affirmative response from node *X* • Arbitration failed - negative response from node *X* • Network partitioning - no arbitrator available • Network partitioning - no arbitrator configured
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	

LCP takeover completed (state = *X*)	7	INFO	
Report whether an arbitrator is found or not	6	INFO	There are 7 different possible outcomes when seeking an arbitrator: • Management server restarts arbitration thread [state=*X*] • Prepare arbitrator node *X* [ticket=*Y*] • Receive arbitrator node *X* [ticket=*Y*] • Started arbitrator node *X* [ticket=*Y*] • Lost arbitrator node *X* - process failure [state=*Y*] • Lost arbitrator node *X* - process exit [state=*Y*] • Lost arbitrator node *X* <error msg> [state=*Y*]

`STATISTICS` Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node *X*
Received # of bytes	9	INFO	Mean number of bytes received from node *X*
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute info, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

`ERROR` Events

These events relate to Cluster errors and warnings; the presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node *X* declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	

Missed heartbeats	8	WARNING	Node *X* missed heartbeat #*Y*
General warning events	2	WARNING	

`INFO` Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node *X*
Create log bytes	11	INFO	Log part, log file, MB
General info events	2	INFO	

17.6.4. Single User Mode

Single user mode allows the database administrator to restrict access to the database system to a single MySQL server (SQL node). When entering single user mode all connections to all other MySQL servers are closed gracefully and all running transactions are aborted. No new transactions are allowed to be started.

Once the cluster has entered single user mode, only the designated SQL node is granted access to the database. You can use the `ALL STATUS` command to see when the cluster has entered single user mode.

Example:

```
NDB> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the SQL node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the command above must be a MySQL Server node; An attempt to specify any other type of node will be rejected.

Note: When the above commmand is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. MySQL Servers waiting for a connection (that is, for the cluster to become ready and available), are now permitted to connect. The MySQL Server denoted as the single-user SQL node continues to run (if still connected) during and after the state change.

Example:

```
NDB> EXIT SINGLE USER MODE
```

The recommended way to handle a node failure when running in single user mode is to do either of the following:

- 1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command

3. Restart the cluster's data nodes

or

- Restart database nodes prior to entering single user mode.

17.6.5. On-line Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

17.6.5.1. Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata**: the names and definitions of all database tables.
- **Table records**: the data actually stored in the database tables at the time that the backup was made
- **Transaction log**: a sequential record telling how and when data was stored in the database

Each of these is saved on all nodes participating in the backup. During backup each node saves these three parts into three files on disk:

- `BACKUP-`*`backup_id`*`.`*`node_id`*`.ctl`

  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-`*`backup_id`*`-0.`*`node_id`*`.data`

  A data file containing the table records, which are saved on a per-fragment basis; that is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states to which tables the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-`*`backup_id`*`.`*`node_id`*`.log`

  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records, since different nodes host different database fragments.

In the listing above, *`backup_id`* stands for the backup identifier and *`node_id`* is the unique identifier for the node creating the file.

17.6.5.2. Using The Management Server to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 17.6.5.4, “Configuration for Cluster Backup”.)

To create a backup using the management server involves the following steps:

1. Start the management server (`ndb_mgm`).

2. Execute the command START BACKUP.

3. The management server will reply with the message Start of backup ordered. This means that the management server has submitted the request to the cluster, but has not yet received any response.

4. The management server will reply Backup *backup_id* started, where *backup_id* is the unique identifier for this particular backup. (This identifier will also be saved in the cluster log, if it has not been configured otherwise.) This means that the cluster has received and processed the backup request. It does *not* mean that the backup has been completed.

5. The management server will signal that the backup is finished with the message Backup *backup_id* completed.

To abort a backup already in progress:

1. Start the management server.

2. Execute the command ABORT BACKUP *backup_id*. The number *backup_id* is the identifier of the backup that was included in the response of the management server when the backup was started (in the message Backup *backup_id* started).

3. The management server will acknowledge the abort request with Abort of backup *backup_id* ordered; note that no actual response to this request has yet been received.

4. Once the backup has been aborted, the management server will report Backup *backup_id* has been aborted for reason *XYZ*. This means that the cluster has terminated the backup and that all files related to this backup have been removed from the cluster filesystem.

It is also possible to abort a backup in progress from the system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note: If there is no backup with ID *backup_id* running when it is aborted, the management server does not make any explicit response. However, the fact that an invalid abort command was sent is indicated in the cluster log.

17.6.5.3. How to Restore a Cluster Backup

The cluster restoration program is implemented as a separate command line utility ndb_restore, which reads the files created by the backup and inserts the stored information into the database. The restore program must be executed once for each set of backup files, that is, as many times as there were database nodes running when the backup was created.

The first time you run the restoration program, you also need to restore the metadata; in other words, you must re-create the database tables. (Note that the cluster should have an empty database when starting to restore a backup.) The restore program acts as an API to the cluster and therefore requires a free connection in order to connect to the cluster. This can be verified with the ndb_mgm command SHOW (you can accomplish this from a system shell using ndb_mgm -e SHOW). The switch -c *connectstring* may be used to locate the MGM node (see Section 17.4.4.2, "The MySQL Cluster connectstring", for information on connectstrings). The backup files must be present in the directory given as an argument to the restoration program.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then ndb_restore must be run twice — once for each database node in the cluster where the backup was taken.

Note: For rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. However, the data files must always be applied before the logs.

17.6.5.4. Configuration for Cluster Backup

There are four configuration parameters essential for backup:

- `BackupDataBufferSize`

  Amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

  Amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

  Total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

  Size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Section 17.4, “MySQL Cluster Configuration”.

17.6.5.5. Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or insufficient disk space. You should check that there is enough memory allocated for the backup. Also check that there is enough space on the hard drive partition of the backup target.

`NDB` does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

17.7. Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDB Cluster` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDB Cluster` was designed from the very beginning to allow for the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

Currently the MySQL Cluster codebase includes support for 4 different transporters. Most users today employ TCP/IP over Ethernet since it is ubiquitous. This is also by far the best-tested transporter in MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible since this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: either a custom transporter can be designed to handle

this case, or one can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin [http://www.dolphinics.com/].

17.7.1. Configuring MySQL Cluster to use SCI Sockets

In this section we will show how one can adapt a cluster configured for normal TCP/IP communication to use SCI Sockets instead. This documentation is based on SCI Sockets version 2.3.0 as of 01 October 2004.

Prerequisites

Any machines with which you wish to use SCI Sockets need to be equipped with SCI cards.

It is possible to use SCI Sockets with any version of MySQL Cluster. No special builds are needed since it uses normal socket calls which are already available in MySQL Cluster. However, SCI Sockets are currently supported only on the Linux 2.4 and 2.6 kernels. SCI Transporters have been tested successfully on additional operating systems although we have verified these only with Linux 2.4 to date.

There are essentially four requirements for SCI Sockets:

1. Building the SCI Socket libraries.
2. Installation of the SCI Socket kernel libraries.
3. Installation of one or two configuration files.
4. The SCI Socket kernel library must enabled either for the entire machine or for the shell where the MySQL Cluster processes are started.

This process needs to be repeated for each machine in the cluster where you plan to use SCI Sockets for inter-node communication.

Two packages need to be retrieved to get SCI Sockets working:

1. The source code package containing the DIS support libraries for the SCI Sockets libraries.
2. The source code package for the SCI Socket libraries themselves.

Currently, these are available only in source code format. The latest versions of these packages at the time of this writing were available as (respectively) `DIS_GPL_2_5_0_SEP_10_2004.tar.gz` and `SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz`. You should be able to find these (or possibly newer versions) at http://www.dolphinics.no/support/downloads.html.

Package Installation

Once you have obtained the library packages, the next step is to unpack them into appropriate directories, with the SCI Sockets library unpacked into a directory below the DIS code. Next, you need to build the libraries. This example shows the commands used on Linux/x86 to perform this task:

```
shell> tar xzf DIS_GPL_2_5_0_SEP_10_2004.tar.gz
shell> cd DIS_GPL_2_5_0_SEP_10_2004/src/
shell> tar xzf ../../SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz
shell> cd ../adm/bin/Linux_pkgs
shell> ./make_PSB_66_release
```

It is possible to build these libraries for some 64-bit procesors. To build the libraries for Opteron

CPUs using the 64-bit extensions, run `make_PSB_66_X86_64_release` rather than `make_PSB_66_release`; if the build is made on an Itanium machine, then you should use `make_PSB_66_IA64_release`. The X86-64 variant should work for Intel EM64T architectures but this has not yet (to our knowledge) been tested.

Once the build process is complete, the compiled libraries will be found in a zipped tar file with a name along the lines of `DIS-<operating-system>-time-date`. It is now time to install the package in the proper place. In this example we will place the installation in `/opt/DIS`. (**Note**: You will most likely need to run the following as the system root user.)

```
shell> cp DIS_Linux_2.4.20-8_181004.tar.gz /opt/
shell> cd /opt
shell> tar xzf DIS_Linux_2.4.20-8_181004.tar.gz
shell> mv DIS_Linux_2.4.20-8_181004 DIS
```

Network Configuration

Now that all the libraries and binaries are in their proper place, we need to ensure that the SCI cards have proper node IDs within the SCI address space.

It is also necessary to decide on the network structure before proceeding. There are three types of network structures which can be used in this context:

- A simple one-dimensional ring
- One or more SCI switches with one ring per switch port
- A two- or three-dimensional torus.

Each of these topologies has its own method for providing node IDs. We discuss each of them in brief.

A simple ring uses node IDs which are non-zero multiples of 4: 4, 8, 12,...

The next possibility uses SCI switches. An SCI switch has 8 ports, each of which can support a ring. It is necessary to make sure that different rings use different node ID spaces. In a typical configuration, the first port uses node IDs below 64 (4 - 60), the next 64 node IDs (68 - 124) are assigned to the next port, and so on, with node IDs 452 - 508 being assigned to the eighth port.

Two- and three-dimensional torus network structures take into account where each node is located in each dimension, incrementing by 4 for each node in the first dimension, by 64 in the second dimension, and (where applicable) by 1024 in the third dimension. See Dolphin's Web site [http://www.dolphinics.com/support/index.html] for more thorough documentation.

In our testing we have used switches, although most large cluster installations use 2- or 3-dimensional torus structures. The advantage provided by switches is that, with dual SCI cards and dual switches, it is possible to build with relative ease a redundant network where the average failover time on the SCI network is on the order of 100 microseconds. This is supported by the SCI transporter in MySQL Cluster and is also under development for the SCI Socket implementation.

Failover for the 2D/3D torus is also possible but requires sending out new routing indexes to all nodes. However, this requires only 100 milliseconds or so to complete and should be acceptable for most high-availability cases.

By placing cluster data nodes properly within the switched architecture, it is possible to use 2 switches to build a structure whereby 16 computers can be interconnected and no single failure can hinder more than one of them. With 32 computers and 2 switches it is possible to configure the cluster in such a manner that no single failure can cause the loss of more than two nodes; in this case it is also possible to know which pair of nodes is affected. Thus, by placing the two nodes in separate node groups, it is possible to build a “safe” MySQL Cluster installation.

To set the node ID for an SCI card use the following command in the `/opt/DIS/sbin` directory. In this example `-c 1` refers to the number of the SCI card (this will always be 1 if there is only 1 card in the machine), `-a 0` refers to adapter 0; and `68` is the node ID:

```
shell> ./sciconfig -c 1 -a 0 -n 68
```

If you have multiple SCI cards in the same machine, you can determine which card has which slot by issuing the following command (again we assume that the current working directory is `/opt/DIS/sbin`):

```
shell> ./sciconfig -c 1 -gsn
```

This will give you the SCI card's serial number. Then repeat this procedure with `-c 2`, and so on, for each card in the machine. Once you have matched each card with a slot, you can set node IDs for all cards.

After the necessary libraries and binaries are installed, and the SCI node IDs are set, the next step is to set up the mapping from hostnames (or IP addresses) to SCI node IDs. This is done in the SCI sockets configuration file, which should be saved as `/etc/sci/scisock.conf`. In this file, each SCI node ID is mapped through the proper SCI card to the hostname or IP address that it is to communicate with. Here is a very simple example of such a configuration file:

```
#host           #nodeId
alpha           8
beta            12
192.168.10.20   16
```

It is also possible to limit the configuration so that it applies only to a subset of the available ports for these hosts. An additional configuration file `/etc/sci/scisock_opt.conf` can be used to accomplish this, as shown here:

```
#-key                        -type        -values
EnablePortsByDefault                yes
EnablePort                  tcp          2200
DisablePort                 tcp          2201
EnablePortRange             tcp          2202 2219
DisablePortRange            tcp          2220 2231
```

Driver Installation

With the configuration files in place, the drivers can be installed.

First, the low-level drivers and then the SCI socket driver need to be installed:

```
shell> cd DIS/sbin/
shell> ./drv-install add PSB66
shell> ./scisocket-install add
```

If desired, the installation can be checked by invoking a script which verifies that all nodes in the SCI socket configuration files are accessible:

```
shell> cd /opt/DIS/sbin/
shell> ./status.sh
```

If you discover an error and need to change the SCI socket configuration, it is necessary to use the `ksocketconfig` to accomplish this task:

```
shell> cd /opt/DIS/util
shell> ./ksocketconfig -f
```

Testing the Setup

To ensure that SCI sockets are actually being used, you can employ the `latency_bench` test program. Using this utility's server component, clients can connect to the server in order to test the latency of the connection; determining whether or not SCI is enabled should be fairly simple from observing the latency. (**Note**: Before using `latency_bench`, it is necessary to set the `LD_PRELOAD` environment variable as shown later in this section.)

To set up a server, use the following:

```
shell> cd /opt/DIS/bin/socket
shell> ./latency_bench -server
```

To run a client, use `latency_bench` again, except this time with the `-client` option:

```
shell> cd /opt/DIS/bin/socket
shell> ./latency_bench -client server_hostname
```

SCI socket configuration should now be complete and MySQL Cluster ready to use both SCI Sockets and the SCI transporter (see Section 17.4.4.10, “MySQL Cluster SCI Transport Connections”).

Starting the Cluster

The next step in the process is to start MySQL Cluster. To enable usage of SCI Sockets it is necessary to set the environment variable `LD_PRELOAD` before starting `ndbd`, `mysqld`, and `ndb_mgmd`. This variable should point to the kernel library for SCI Sockets.

To start `ndbd` in a bash shell, do the following:

```
bash-shell> export LD_PRELOAD=/opt/DIS/lib/libkscisock.so
bash-shell> ndbd
```

In a tcsh environment the same thing can be accomplished with:

```
tcsh-shell> setenv LD_PRELOAD=/opt/DIS/lib/libkscisock.so
tcsh-shell> ndbd
```

Note: MySQL Cluster can use only the kernel variant of SCI Sockets.

17.7.2. Understanding the Impact of Cluster Interconnects

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access**

  This is the simple access of a record through its primary key. In the simplest case only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses will share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, then additional TCP/IP messages need to be set up.

- **Unique key access**

Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by ndbd. Such requests also benefit from batching.

- **Full table scan**

  When no indexes exist for a lookup on a table, then a full scan of a table is performed. This is sent as a single request to the ndbd process, which then divides the table scan into a set of parallel scans on all cluster ndbd processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index**

  When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

To check the base performance of these access methods we have developed a set of benchmarks. One such benchmark, testReadPerf, tests simple and batched primary and unique key accesses. This benchmark also measures the setup cost of range scans by issuing scans returning a single record. There is also a variant of this benchmark which uses a range scan to fetch a batch of records.

In this way, we can determine the cost of both a single key access and a single record scan access, as well as measure the impact of the communication media used, on base access methods.

In our tests, we ran the base benchmarks for both a normal transporter using TCP/IP sockets and a similar setup using SCI sockets. The figures reported below are for small accesses of 20 records per access. The difference between serial and batched access decreases by a factor of 3 to 4 when using 2 kB records instead. SCI Sockets were not tested with 2 kB records. Tests were performed on a cluster with 2 data nodes running on 2 dual-CPU machines equipped with AMD MP1900+ processors.

```
Access type:          TCP/IP sockets          SCI Socket
Serial pk access:     400 microseconds        160 microseconds
Batched pk access:     28 microseconds         22 microseconds
Serial uk access:     500 microseconds        250 microseconds
Batched uk access:     70 microseconds         36 microseconds
Indexed eq-bound:    1250 microseconds        750 microseconds
Index range:           24 microseconds         12 microseconds
```

We also performed another set of tests to check the performance of SCI Sockets vis-à-vis that of the SCI transporter, and both of these as compared with the TCP/IP transporter. All these tests used primary key accesses either serially and multi-threaded, or multi-threaded and batched.

The tests showed that SCI sockets were about 100% faster than TCP/IP. The SCI transporter was faster in most cases compared to SCI sockets. One notable case occurred with many threads in the test program, which showed that the SCI transporter did not perform very well when used for the mysqld process.

Our overall conclusion was that, for most benchmarks, using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case the CPU processing in the ndbd processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between ndbd processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the ndbd process since the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the ndbd process priority is set in such a way that the process does not lose

priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, then the `ndbd` process will benefit by 10-70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. We have tested MySQL Cluster so far only with SCI sockets. We also include documentation above on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

17.8. Known Limitations of MySQL Cluster

In this section, we provide a listing of known limitations in MySQL Cluster releases in the 5.1.x series when compared to features available when using the `MyISAM` and `InnoDB` storage engines. Currently there are no plans to address these in coming releases of MySQL 5.1; however, we will attempt to supply fixes for these issues in subsequent release series. If you check the "Cluster" category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs which (if marked "5.1") we intend to correct in upcoming releases of MySQL 5.1.

(**Note**: See the end of this section for a list of issues in MySQL 5.0 Cluster that have been resolved in the current version.)

- **Noncompliance in syntax** (resulting in errors when running existing applications):
  - Text indexes are not supported.
  - Geometry datatypes (`WKT` and `WKB`) are supported in `NDB` tables in MySQL 5.1; however, spatial indexes are not supported.
- **Non-compliance in limits or behavior** (may result in errors when running existing applications):
  - **Transaction Handling**:
    - `NDB Cluster` supports only the `READ_COMMITTED` transaction isolation level.
    - There is no partial rollback of transactions. A duplicate key or similar error will result in a rollback of the entire transaction.
    - **Important**: If a `SELECT` from a Cluster table includes a `BLOB`, `TEXT`, or `VARCHAR` column, then the `READ_COMMITTED` transaction isolation level is converted to a read with read lock. This is done in order to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.
  - A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 17.4.4, "Configuration File". Most configuration parameters can be upgraded online. These hard limits include:
    - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).
    - The maximum number of transactions that can be performed is set using the configuration parameter `MaxNoOfConcurrentOperations`. Note that bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.
    - Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by `MaxNoOfOrderedIndexes`.
  - Database names, table names and attribute names cannot be as long in `NDB` tables as with other table handlers. Attribute names are truncated to 31 characters, and if not unique after

truncation give rise to errors. Database names and table names can total a maximum of 122 characters. (That is, the maximum length for an `NDB Cluster` table name is 122 characters less the number of characters in the name of the database of which that table is a part.)

- All Cluster table rows are of fixed length. This means (for example) that if a table has one or more `VARCHAR` fields containing only relatively small values, more memory and disk space is required when using the `NDB` storage engine than would be for the same table and data using the `MyISAM` engine. (In other words, in the case of a `VARCHAR` column, the column requires the same amount of storage as a `CHAR` column of the same size.)

- The maximum number of tables in a Cluster database is limited to 1792.

- The maximum number of attributes per table is limited to 128.

- The maximum permitted size of any one row is 8k, *not including data stored in `BLOB` columns*.

- The maximum number of attributes per key is 32.

- **Unsupported features** (do not cause errors, but are not supported or enforced):

  - The foreign key construct is ignored, just as it is in `MyISAM` tables.

  - Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.

- **Performance and limitation-related issues**:

  - There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.

  - The `Records in range` statistic is not supported, resulting in non-optimal query plans in some cases. Employ `USE INDEX` or `FORCE INDEX` as a workaround.

  - Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

  - MySQL Cluster does not support durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Missing features**:

  - The only supported isolation level is `READ_COMMITTED`. (InnoDB supports `READ_COMMITTED`, `READ_COMMITTED`, `REPEATABLE_READ`, and `SERIALIZABLE`.) See Section 17.6.5.5, “Backup Troubleshooting”, for information on how this can effect backup and restore of Cluster databases.

  - No durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Problems relating to multiple MySQL servers** (not relating to `MyISAM` or `InnoDB`):

  - `ALTER TABLE` is not fully locking when running multiple MySQL servers (no distributed table lock).

  - MySQL replication will not work correctly if updates are done on multiple MySQL servers. However, if the database partitioning scheme is done at the application level, and no transactions take place across these partitions, then replication can be made to work.

  - Autodiscovery of databases is not supported for multiple MySQL servers accessing the same MySQL Cluster. However, autodiscovery of tables is supported in such cases. What this means is that after a database named *`db_name`* is created or imported using one MySQL server, you should issue a `CREATE SCHEMA` *`db_name`*`;` statement on each additional

MySQL server that access the same MySQL Cluster. Once this has been done for a given MySQL server, that server should be able to detect the database tables without error.

- **Issues exclusive to MySQL Cluster** (not related to `MyISAM` or `InnoDB`):

  - All machines used in the cluster must have the same architecture; that is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.

  - It is not possible to make online schema changes such as those accomplished using `ALTER TABLE` or `CREATE INDEX`, as the `NDB Cluster` does not support autodiscovery of such changes. (However, you can import or create a table that uses a different storage engine, then convert it to `NDB` using `ALTER TABLE` *`tbl_name`* `ENGINE=NDBCLUSTER;`. In such a case, you need to issue a `FLUSH TABLES` command in order to force the cluster to pick up the change.)

  - Online adding or dropping of nodes is not possible (the cluster must be restarted in such cases).

  - When using multiple management servers:

    - You must give nodes explicit IDs in connectstrings since automatic allocation of node IDs does not work across multiple management servers.

    - You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

    - In order that management nodes be able to see one another, you must restart all data nodes after bringing up the cluster. (See Bug #13070 [http://bugs.mysql.com/13070] for a detailed explanation.)

  - Multiple network interfaces for data nodes are not supported. Use of these is liable to cause problems because, in the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it since another route to that data node remains open. This can effectively make the cluster inoperable.

  - The maximum number of data nodes is 48.

  - The total maximum number of nodes in a MySQL Cluster is 63. This number includes all MySQL Servers (SQL nodes), data nodes, and management servers.

  - The maximum number of metadata objects in MySQL 5.1 Cluster is 20320. This limit is hard-coded.

The above listing is intended to be complete with respect to the conditions set forth at the beginning of this section. You can report any discrepancies that you encounter to the MySQL bugs database at http://bugs.mysql.com/. If we do not plan to fix the problem in MySQL 5.1, we will add it to the list.

17.9. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1 as compared to MySQL 5.0. We will also discuss our roadmap for further improvements to MySQL Cluster as currently planned for MySQL 5.2.

There are relatively few changes between the NDB Cluster storage engine implementations in MySQL 5.0 and in 5.1, so the upgrade path should be relatively quick and painless.

All significantly new features being developed for MySQL Cluster are going into the MySQL 5.1 tree. We also provide some hints about what Cluster in MySQL 5.1 is likely to include later in this

section (see Section 17.9.2, “MySQL 5.1 Development Roadmap for MySQL Cluster”).

17.9.1. MySQL Cluster Changes in MySQL 5.0

MySQL 5.0.3-beta and later releases contain a number of new features that are likely to be of interest:

- **Push-Down Conditions**: A query such as

  ```
  SELECT * FROM t1 WHERE non_indexed_attribute = 1;
  ```

  will use a full table scan and the condition will be evaluated in the cluster's data nodes. Thus it is not necessary to send the records across the network for evaluation. (That is, function transport is used, rather than data transport.) For this type of query you should see a speed up factor of 5-10. Please note that this feature is currently disabled by default (pending more thorough testing), but it should work in most cases. This feature can be enabled through the use of the command `SET engine-condition-pushdown=On;` command. Alternatively, you can run `mysqld` with the this feature enabled by starting the MySQL server with the new `--engine-condition-pushdown` option flag.

  You can use `EXPLAIN` to determine when push-down conditions are being used.

  A major benefit of this change is that queries are now executed in parallel. This means that queries against non-indexed columns can run as much as 5 to 10 times, *times the number of data nodes*, faster than previously, since multiple CPUs can work on the query in parallel.

- **Decreased `IndexMemory` Usage**: In MySQL 5.1, each record consumes approximately 25 bytes of index memory, and every unique index uses 25 bytes per record of index memory (in addition to some data memory since these are stored in a separate table). This is because there is no storage of the primary key in the index memory anymore.

- **Query Cache Enabled for MySQL Cluster**: See Section 5.13, “The MySQL Query Cache”, for information on configuring ans using the query cache.

- **New Optimizations**: One optimization that merits particular attention is that a batched read interface is now used in some queries. For example, consider the following query:

  ```
  SELECT * FROM t1 WHERE primary_key IN (1,2,3,4,5,6,7,8,9,10);
  ```

  This query will be executed 2 to 3 times more quickly than in previous MySQL Cluster versions due to the fact that all 10 key lookups are sent in a single batch rather than one at a time.

- **Limit On Number of Metadata Objects**: In MySQL 5.1, each Cluster database may contain a maximum of 20320 metadata objects, including database tables, system tables, indexes and `BLOB`s.

17.9.2. MySQL 5.1 Development Roadmap for MySQL Cluster

What is said here is a status report based on recent commits to the MySQL 5.1 source tree. It should be noted all 5.1 development is subject to change.

There are currently 4 major new features being developed for MySQL 5.1:

1. **Integration of MySQL Cluster into MySQL Replication**: This will make it possible to update from any MySQL Server in the cluster and still have the MySQL Replication handled by one of the MySQL Servers in the cluster and the installation on the slave side consistent.

2. **Support for disk-based records**: Records on disk will be supported. Indexed fields including the primary key hash index must still be stored in RAM but all other fields can be on disk.

3. **Variable sized records**: A column defined as `VARCHAR(255)` currently uses 260 bytes of storage independent of what is stored in any particular record. In MySQL 5.1 Cluster tables only the portion of the field actually taken up by the record will be stored. This will make possible a reduction in space requirements for such columns by a factor of 5 in many cases.

4. **User-defined Partitioning**: Users will be able to define partitions based on the fields part of the primary key. The MySQL Server will be able to discover whether it is possible to prune away some of the partitions from the `WHERE` clause. Partitioning based on `KEY`, `HASH`, `RANGE`, and `LIST` handlers will be possible, as well as subpartitioning. This feature should also be available for many other handlers.

In addition, we are working to increase the 8k size limit for rows containing columns of types other than BLOB or TEXT in Cluster tables. This is due to the fact that rows are currently fixed in size and the page size is 32,768 bytes (minus 128 bytes for the row header). Currently this means that if we allowed more than 8k per record, any remaining space (up to approximately 14,000 bytes) would be left empty. In MySQL 5.1, we plan to fix this limitation so that using more than 8k in a given row does not result in the remainder of the page being wasted.

17.10. MySQL Cluster FAQ

- *What's the difference in using Cluster vs. using replication?*

  In a replication setup, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as `InnoDB` is being used, then a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In MySQL Cluster, all data nodes are kept in synch, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes will remain in a consistent state.

  In short, whereas standard MySQL replication is asynchronous, MySQL Cluster is synchronous.

  We are planning to implement (asynchronous) replication for Cluster in MySQL 5.1. This will include the capability to replicate both between two clusters and between a MySQL cluster and a non-Cluster MySQL server.

- *Do I need to do any special networking to run Cluster? (How do computers in a cluster communicate?)*

  MySQL Cluster is intended to be used in a high-bandwidth environment, with computers connecting via TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

  The faster SCI protocol is also supported, but requires special hardware. See Section 17.7, “Using High-Speed Interconnects with MySQL Cluster”, for more information about SCI.

- *How many computers do I need to run a cluster, and why?*

  A minimum of three computers is required to run a viable cluster. However, the minimum **recommended** number of computers in a MySQL Cluster is four: one each to run the management and SQL nodes, and two computers to serve as storage nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine in order to guarantee continued arbitration services in the event that one of the data nodes fails.

- *What do the different computers do in a cluster?*

  A MySQL Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. Ideally, there will be one node per cluster host, although it is possible to run multiple nodes on a single host. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

  1. **management node (MGM node)**: Provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control MySQL Cluster via the MGM node is `ndb_mgm`.

  2. **data node**: Stores and replicates data. Data node functionality is handled by an instance of the NDB data node process `ndbd`.

  3. **SQL node**: This is simply an instance of MySQL Server (`mysqld`) started with the `--ndb-cluster` option.

- *With which operating systems can I use Cluster?*

  In MySQL 5.1, MySQL Cluster is officially supported on Linux, Mac OS X, and Solaris. We are working to add Cluster support for other platforms, including Windows, and our goal is eventually to offer MySQL Cluster on all platforms for which MySQL itself is supported.

  It may be possible to run Cluster processes on other operating systems. We have had reports from users who say that they have run Cluster successfully on FreeBSD. However, Cluster on any but the three platforms mentioned here should be considered alpha software (at best), cannot be guaranteed reliable in a production setting, and *is not supported by MySQL AB*.

- *What are the hardware requirements for running MySQL Cluster?*

  Cluster should run on any platform for which NDB-enabled binaries are available. Naturally, faster CPUs and more memory will improve performance, and 64-bit CPUs will likely be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node's share of the database (see **How much RAM do I Need?** for more info). Nodes can communicate via a standard TCP/IP network and hardware. For SCI support, special networking hardware is required.

- *Since MySQL Cluster uses TCP/IP, does that mean I can run it over the Internet, with one or more nodes in a remote location?*

  It is extremely important to keep in mind that communications between the nodes in a MySQL Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.)

  It is very doubtful in any case that a cluster would perform reliably under such conditions, as MySQL Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet (preferably the latter). We neither test nor warrant its performance using anything slower than this.

- *Do I have to learn a new programming or query language to use Cluster?*

  No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL queries and commands are required for:

  - Creating, altering, and dropping tables

  - Inserting, updating, and deleting table data

  - Creating, changing, and dropping primary and unique indexes
  - Configuring and managing SQL nodes (MySQL servers)

- *How do I find out what an error or warning message means when using Cluster?*

  There are two ways in which this can be done:

  1. From within the MySQL Monitor, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition. These can also be displayed in MySQL Query Browser.

  2. From a system shell prompt, use `perror --ndb error_code`.

- *Is MySQL Cluster transaction-safe? What isolation levels are supported?*

  Yes: For tables created with the `NDB` storage engine, transactions are supported. In MySQL 5.1, Cluster supports only the `READ_COMMITTED` transaction isolation level.

- *What storage engines does Cluster support?*

  `NDB` is the only MySQL storage engine that supports clustering.

  (It is possible to create tables using other storage engines such as `MyISAM` or `InnoDB` on a MySQL server being used for clustering, but these non-`NDB` tables will **not** participate in the cluster.)

- *What does "NDB" mean?*

  This stands for "**N**etwork **D**ata**b**ase".

- *Which versions of the MySQL software support Cluster? Do I have to compile from source?*

  Cluster is supported in all MySQL-max binaries in the 5.1 release series, except as noted in the following paragraph. You can determine whether or not your server has NDB support using either of the commands `SHOW VARIABLES LIKE 'have_%';` or `SHOW ENGINES;`. (See Section 5.1.2, "The `mysqld-max` Extended MySQL Server", for more information.)

  Linux users, please note that `NDB` is *not* included in the standard MySQL server RPMs. There are also separate RPM packages for the NDB storage engine and accompanying management and other tools; see the NDB RPM Downloads section of the MySQL 5.1 Downloads page for these. (Formerly, you had to use the `-max` binaries supplied as `.tar.gz` archives. This is still possible, but is not required, so you can use your Linux distribution's RPM manager if you prefer.) You can also obtain NDB support by compiling the `-max` binaries from source, but it is not necessary to do so simply to use MySQL Cluster. To download the latest binary, RPM, or source distibution in the MySQL 5.1 series, visit http://dev.mysql.com/downloads/mysql/5.1.html.

- *How much RAM do I need? Is it possible to use disk memory at all?*

  Currently, Cluster is in-memory only. This means that all table data (including indexes) is stored in RAM. Therefore, if your data takes up 1 gigabyte of space and you wish to replicate it once in the cluster, you need 2 gigabytes of memory to do so. This in addition to the memory required by the operating system and any applications running on the cluster computers.

  You can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

  ```
  (SizeofDatabase * NumberOfReplicas * 1.1 ) / NumberOfDataNodes
  ```

  To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.5, "Data Type Storage Re-

quirements", for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an `NDBCluster` table requires 21-25 bytes per record. These indexes use `IndexMemory`.
- Each ordered index requires 10 bytes storage per record, using `DataMemory`.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with `USING HASH`. In other words, if created without `USING HASH`, a primary key or unique index on a Cluster table takes up 31-35 bytes per record in MySQL 5.1.

  Note that creating MySQL Cluster tables with `USING HASH` for all primary keys and unique indexes will generally cause table updates to run more quickly. This is due to the fact that less memory is required (since no ordered indexes are created), and that less CPU must be utilized (since fewer indexes must be read and possibly updated).

It is especially important to keep in mind that *every MySQL Cluster table must have a primary key*. The `NDB` storage engine creates a primary key automatically if none is defined, and this primary key is created without `USING HASH`.

There is no easy way to determine exactly how much memory is being used for storage of Cluster indexes at any given time; however, warnings are written to the Cluster log when 80% of available `DataMemory` or `IndexMemory` is in use, and again when 85%, 90%, and so on is in use.

We often see questions from users who report that, when they are trying to populate a Cluster database, the loading process terminates prematurely and an error message like this one is observed:

```
ERROR 1114: The table 'my_cluster_table' is full
```

When this occurs, the cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, *including the primary key required by the `NDB` storage engine and automatically created in the event that the table definition does not include the definition of a primary key*.

It is also worth noting that all data nodes should have the same amount of RAM, as no data node in a cluster can use more memory than the least amount available to any individual data node. In other words, if there are three computers hosting Cluster data nodes, with two of these having three gigabytes of RAM available to store Cluster data, and one having only one GB RAM, then each data node can devote only one GB to clustering.

- *In the event of a catastrophic failure — say, for instance, the whole city loses power **and** my UPS fails — would I lose all my data?*

  All committed transactions are logged. Therefore, while it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

- *Is it possible to use `FULLTEXT` indexes with Cluster?*

  `FULLTEXT` indexing is not currently supported by the `NDB` storage engine, or by any storage engine other than `MyISAM`. We are working to add this capability in a future release.

- *Can I run multiple nodes on a single computer?*

  It is possible but not advisable. One of the chief reasons to run a cluster is to provide redundancy; in order to enjoy the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. Given that MySQL Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, it is well worth the expense of an extra machine or two

in order to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal; this task can be accomplished with a 200 MHz Pentium CPU and sufficient RAM for the operating system plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

- *Can I add nodes to a cluster without restarting it?*

  Not at present. A simple restart is all that is required for adding new MGM or SQL nodes to a Cluster. When adding data nodes the process is more complex, and requires the following steps:

  - Make a complete backup of all Cluster data.
  - Completely shut down the cluster and all cluster node processes.
  - Restart the cluster, using the `--initial` startup option.
  - Restore all cluster data from the backup.

  In a future MySQL Cluster release series, we hope to implement a "hot" reconfiguration capability for MySQL Cluster in order to minimize (if not eliminate) the requirement for restarting the cluster when adding new nodes.

- *Are there any limitations that I should be aware of when using Cluster?*

  `NDB` tables in MySQL are subject to the following limitations:

  - Not all character sets and collations are supported.
  - `FULLTEXT` indexes and prefix indexes are not supported. Only complete columns may be indexed.
  - Chapter 19, *Spatial Extensions in MySQL*, are not supported.
  - Only complete rollbacks for transactions are supported. Partial rollbacks and rollbacks to savepoints are not supported.
  - The maximum number of attributes allowed per table is 128, and attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
  - The maximum size for a table row is 8 kilobytes, not counting `BLOB`s. There is no set limit for the number of rows per table; table size limits depend on a number of factors, in particular on the amount of RAM available to each data node.
  - The `NDB` engine does not support foreign key constraints. As with `MyISAM` tables, these are ignored.
  - Query caching is not supported.

  For additional information on Cluster limitations, see Section 17.8, "Known Limitations of MySQL Cluster".

- *How do I import an existing MySQL database into a cluster?*

  You can import databases into MySQL Cluster much as you would with any other version of MySQL. Other than the limitation mentioned in the previous question, the only other special requirement is that any tables to be included in the cluster must use the `NDB` storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`. It is also possible to convert existing tables using other storage engines to `NDB Cluster` using `ALTER TABLE`, but requires an additional workaround; see Section 17.8, "Known Limitations of MySQL Cluster", for details.

- *How do cluster nodes communicate with one another?*

Cluster nodes can communicate via any of three different protocols: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 17.7, "Using High-Speed Interconnects with MySQL Cluster", for more about using SCI as a transport mechanism in MySQL Cluster.

- *What is an "arbitrator"?*

  If one or more nodes in a cluster fail, it is possible that not all cluster nodes will not be able to "see" one another. In fact, it is possible that two sets of nodes might become isolated from one another in a network partitioning, also known as a "split brain" scenario. This type of situation is undesirable because each set of nodes tries to behave as though it is the entire cluster.

  When cluster nodes go down, there are two possibilities. If more than 50% of the remaining nodes can communicate with each other, then we have what is sometimes called a "majority rules" situation, and this set of nodes is considered to be the cluster. The arbitrator comes into play when there is an even number of nodes: in such cases, the set of nodes to which the arbitrator belongs is considered to be the cluster, and nodes not belonging to this set are shut down.

  The above information is somewhat simplified; a more complete explanation taking into account node groups follows below:

  When all nodes in at least one node group are alive, network partitioning is not an issue, because no one portion of the cluster can form a functional cluster. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the "split-brain" scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. (See Section 17.4.4.4, "Defining the MySQL Cluster Management Server", for details.) It should also be noted that the role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

- *What data types are supported by MySQL Cluster?*

  MySQL Cluster supports all of the usual MySQL data types, with the exception of those associated with MySQL's spatial extensions. (See Chapter 19, *Spatial Extensions in MySQL*.) In addition, there are some differences with regard to indexes when used with `NDB` tables. **Note**: MySQL Cluster tables (that is, tables created with `ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each record containing a `VARCHAR(255)` column will require 256 bytes of storage for that column, regardless of the size of the data stored therein. This issue is expected to be fixed in a future MySQL release series.

  See Section 17.8, "Known Limitations of MySQL Cluster", for more information about these issues.

- *How do I start and stop MySQL Cluster?*

  It is necessary to start each node in the cluster separately, in the following order:

  1. Start the management node with the `ndb_mgmd` command.

  2. Start each data node with the `ndbd` command.

  3. Start each MySQL server (SQL node) using `mysqld_safe --user=mysql &`.

  Each of these commands must be run from a system shell on the machine housing the affected node. You can verify the cluster is running by starting the MGM management client `ndb_mgm` on the machine housing the MGM node.

- *What happens to cluster data when the cluster is shut down?*

  The data held in memory by the cluster's data nodes is written to disk, and is reloaded in memory the next time that the cluster is started.

  To shut down the cluster, enter the following in a shell on the machine hosting the MGM node:

  ```
  shell> ndb_mgm -e shutdown
  ```

  This will cause the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as Cluster SQL nodes can be stopped using `mysqladmin shutdown`.

  For more information, see Section 17.6.2, “Commands in the Management Client”, and Section 17.3.6, “Safe Shutdown and Restart”.

- *Is it helpful to have more than one management node for a cluster?*

  It can be helpful as a fail-safe. Only one MGM node controls the cluster at any given time, but it is possible to configure one MGM as primary, and one or more additional management nodes to take over in the evnt that the primary MGM node fails.

- *Can I mix different kinds of hardware and operating systems in a Cluster?*

  Yes, so long as all machines and operating systems are the same endian. It is also possible to use different MySQL Cluster releases on different nodes; however, we recommend this be done only as part of a rolling upgrade procedure.

- *Can I run two data nodes on a single host? Two SQL nodes?*

  Yes, it is possible to do this. In the case of multiple data nodes, each node must use a different data directory. If you want to run multiple SQL nodes on one machine, then each instance of `mysqld` must use a different TCP/IP port.

- *Can I use hostnames with MySQL Cluster?*

  Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, we recommend using fixed IP addresses. Making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional points of failure, and the fewer of these, the better.

17.11. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster**:

  In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.

  `NDB Cluster`:

  This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.

  MySQL Cluster:

  This refers to a group of computers working together using the `NDB` storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.

- **Configuration files**:

  Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See Section 17.4.4, “Configuration File”, for details.

- **Backup**:

  A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.

- **Restore**:

  Returning the cluster to a previous state, as stored in a backup.

- **Checkpoint**:

  Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two sorts of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:

  - **Local Checkpoint (LCP)**:

    This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

  - **Global Checkpoint (GCP)**:

    A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

- **Cluster host**:

  A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*. See also **Node** and **Node group** below.

- **Node**:

  This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQl Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster. These are:

  - **Management (MGM) nodes**:

    Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.

  - **SQL (MySQL server) nodes**:

    Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual authentication methods and API's; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.

  - **Data nodes**:

These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or functional component (that is, a process).

Note Regarding Obsolete Terms: In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes”, “DB nodes”, or occasionally “storage nodes”. In addition, SQL nodes were sometimes known as “client nodes” or “API nodes”. This older terminology has been deprecated in order to minimize confusion, and for these reasons should be avoided.

- **Node group**:

  A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

- **Node failure**:

  MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's configuration.

- **Node restart**:

  The process of restarting a failed cluster node.

- **Initial node restart**:

  The process of starting a cluster node with its filesystem removed. This is sometimes used in the course of software upgrades and in other special circumstances.

- **System crash** (or **system failure**):

  This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.

- **System restart**:

  The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.

- **Fragment**:

  A portion of a database table; in the `NDB` storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.

- **Replica**:

  Under the `NDB` storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently there may be up 4 replicas per fragment.

- **Transporter**:

A protocol providing data transfer between nodes. MySQL Cluster currently supports 4 different types of transporter connections:

- TCP/IP (local)

  This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet.

- TCP/IP (remote)

  Same as above, except as used for communicating remotely.

- SCI

  Scalable **C**oherent **I**nterface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware and is discussed in Section 17.7.1, “Configuring MySQL Cluster to use SCI Sockets”. For a basic introduction to SCI, see this essay at dolphinics.com [http://www.dolphinics.com/corporate/scitech.html].

- SHM

  Unix-style **sh**ared **m**emory segments. Where supported, SHM is used automatically to connect nodes running on the same host. The Unix man page for `shmop(2)` [http://www.scit.wlv.ac.uk/cgi-bin/mansec?2+shmop] is a good place to begin obtaining additional information about this topic.

Note: The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix sockets or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL APIs.

- **`NDB`**:

  This stands for **N**etwork **D**ata**b**ase, and refers to the storage engine used to enable MySQL Cluster. The `NDB` storage engine supports all the usual MySQL data types and SQL statements, and is ACID-compliant. This engine also provides full support for transactions (commits and rollbacks).

- **Share-nothing architecture**:

  The ideal architecture for a MySQL Cluster. In a true share-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.

- **In-memory storage**:

  All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1 gigabyte of memory, and you wish to set up the cluster with 4 replicas and 8 data nodes, a minimum of 500 MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

- **Table**:

  As is usual in the context of a relational database, the term “table” denotes an ordered set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.

- **Cluster programs**:

These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:

- `ndbd`:

  The data node daemon (runs a data node process)

- `ndb_mgmd`:

  The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

  The management client (provides an interface for executing management commands)

- `ndb_waiter`:

  Used to verify status of all nodes in a cluster

- `ndb_restore`:

  Restores cluster data from backup

For more about these programs and their uses, see Section 17.5, “Process Management in MySQL Cluster”.

- **Event log**:

  MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 17.6.3, “Event Reports Generated in MySQL Cluster”. Event logs are of two types:

  - **Cluster log**:

    Keeps a record of all desired reportable events for the cluster as a whole.

  - **Node log**:

    A separate log which is also kept for each individual node.

  Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Chapter 18. Partitioning

This chapter discusses partitioning as implemented in MySQL 5.1. An introduction to partitioning and partitioning concepts may be found in Section 18.1, “Overview of Partitioning in MySQL”. MySQL 5.1 supports several types of partitioning, which are discussed in Section 18.2, “Partition Types”, as well as subpartitioning (also known sometimes as composite partitioning), which is described in Section 18.2.5, “Subpartitioning”. Methods of adding, removing, and altering partitions in existing partitioned tables are covered in Section 18.3, “Partition Management”. Table maintenance commands for use with partitioned tables are discussed in Section 18.3.3, “Maintenance of Partitions”.

Please Note: The partitioning implementation in MySQL 5.1 is still very new (pre-alpha quality) and is *not* production-ready at this time. Much the same is true of this chapter: Some of the features described herein are not yet actually implemented (partitioning maintenance and repartitioning commands), and others might not yet function exactly as described (for example, the `DATA DIRECTORY` and `INDEX DIRECTORY` options for partitions are adversely affected by Bug #13520 [http://bugs.mysql.com/13520]). We have attempted to note these discrepancies in this chapter. Before filing bug reports, we encourage you to check the following resources:

- MySQL Partitioning Forum [http://forums.mysql.com/list.php?106]

  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- Partitioning Bug Reports [http://tinyurl.com/9wy6h]

  A list of all Partitioning bugs that have been filed in our Bugs System, regardless of age, severity, or current status. It is possible to filter this list according to a number of criteria, or you may wish to start from the MySQL Bugs System Home Page [http://bugs.mysql.com/] and search for bugs which are of particular interest to you.

- Mikael Ronström's Blog [http://mikaelronstrom.blogspot.com/]

  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- PlanetMySQL [http://www.planetmysql.org/]

  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

A MySQL 5.1 alpha binary is now available. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our BitKeeper repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see Section 2.8, “MySQL Installation Using a Source Distribution”. If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the MySQL Partitioning Forum [http://forums.mysql.com/list.php?106] and ask for assistance there if you don't find a solution to your problem already posted.

18.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical loca-

tion to be used for storing specific pieces of data in terms of the filesystem, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 7.6.1, “Using Symbolic Links”, for an explanation of how this is done).

Partitioning takes this notion a step further, by allowing you to distribute portions of individual tables across a filesystem according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be non-constant and non-random. It may not contain any queries, but may use virtually any SQL expression that is valid in MySQL, so long as that expression returns a positive integer less than MAXVALUE (the greatest possible positive integer). Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see Section 18.2, “Partition Types”), as well as in the partitioning syntax descriptions given in Section 13.1.5, “CREATE TABLE Syntax”.

This is known as *horizontal partitioning* — that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

Partitioning support is included in the -max releases of MySQL 5.1 (that is, the 5.1 -max binaries will be built with --with-partition). If the MySQL binary is built with partitioning support, nothing further needs to be done in order to enable it (for example, no special entries are required in your my.cnf file). You can determine whether or not your MySQL server supports partitioning by means of a SHOW VARIABLES command such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';

+-----------------------+-------+
| Variable_name         | Value |
+-----------------------+-------+
| have_partition_engine | YES   |
+-----------------------+-------+
1 row in set (0.00 sec)
```

If you do not see the have_partition_engine variable with the value YES listed as shown above in the output of an appropriate SHOW VARIABLES, then your version of MySQL does not support partitioning. (Note that there is nothing in the output of SHOW ENGINES that displays any information relating to partitioning support; you must use SHOW VARIABLES to make this determination.)

For creating partitioned tables, you can use any storage engine that is supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use MyISAM for one partition and InnoDB for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

To employ a particular storage engine for a partitioned table, it is necessary only to use the [STORAGE] ENGINE option just as you would for a non-partitioned table. However, you should keep in mind that [STORAGE] ENGINE (and other table options) need to be listed *before* any partitioning options are used in a CREATE TABLE statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the InnoDB storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
```

```
ENGINE=INNODB
PARTITION BY HASH(MONTH(tr_date))
PARTITIONS 6;
```

(Note that each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.1 this has no effect.)

It is possible to create partitioned temporary tables; however, the lifetime of such tables is only as long as the current MySQL session. This is the same as for non-partitioned temporary tables.

Note: Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the PARTITION clause of the `CREATE TABLE` statement used to create the partitioned table. In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See Section 18.3, "Partition Management", for more information on these options. **Note**: This particular feature is currently nonfunctional due to Bug #13250 [http://bugs.mysql.com/13250]; we should have this fixed by the time the first 5.1 binaries are made available.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or filesystem partition.
- Data that loses its usefulness can often be easily be removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for that data.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities; we hope to include them in the 5.1 production release.

- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up.
- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By "parallelized", we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this page and chapter frequently for updates as Partitioning development for MySQL 5.1 continues.

18.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include:

- **`RANGE` partitioning**: Assigns rows to partitions based on column values falling within a given range. See Section 18.2.1, "`RANGE` Partitioning".

- **`LIST` partitioning**: Similar to partitioning by range, except that the partition is selected based on columns matching one of a set of discrete values. See Section 18.2.2, "`LIST` Partitioning".

- **`HASH` partitioning**: A partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a non-negative integer value. See Section 18.2.3, "`HASH` Partitioning".

- **`KEY` partitioning**: Similar to partitioning by hash, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. The column or columns must contain only integers values. See Section 18.2.4, "`KEY` Partitioning".

It is important to remember — regardless of the type of partitioning that you use — that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to insure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than `0`. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->     PARTITION mypart VALUES IN (1,3,5),
    ->     PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): All partitions must have unique names in the table
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 13.1.5, "`CREATE TABLE` Syntax".

18.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a `switch ... case` in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results since the server does not know where to place it. You can keep this from occurring by using a "catchall" `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than highest value explicitly named:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

`MAXVALUE` represents the greatest possible integer value. Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future — when the number of stores has increased to 25, 30, or more — you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Section 18.3, "Partition Management", for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes — that is, based on ranges of `job_code` column values. For example — assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions — you could create the partitioned table using the following:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
```

```
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. The most noteworthy restriction here is that MySQL must be able to evaluate the expression's return value as part of a `LESS THAN` (`<`) comparison; thus, the expression's value cannot be `NULL`. It is for this reason that the `hired`, `separated`, `job_code`, and `store_id` columns of the `employees` table have been defined as `NOT NULL`.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company, that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.2, “`ALTER TABLE` Syntax”, and Section 18.3, “Partition Management”, for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `SELECT COUNT(*) FROM employees WHERE YEAR(separated) = 2000 GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. **Note**: This optimization has not yet been enabled in the MySQL 5.1 sources; however, work is in progress.

18.2.2. LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by RANGE, each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using PARTITION BY LIST(*expr*) where *expr* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a VALUES IN (*value_list*), where *value_list* is a comma-separated list of integers.

Note: In MySQL 5.1, it is possible to match against only a list of integers when partitioning by LIST.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.5, "CREATE TABLE Syntax".

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the CREATE TABLE statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
);
```

(This is the same table used as a basis for the examples in Section 18.2.1, "RANGE Partitioning".)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table:

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the CREATE TABLE statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table.

For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest;`, which can be executed much more efficiently than the equivalent `DELETE` query `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`.

Important: If you try to insert a row such that the column value (or the partitioning expression's return value) is not found in any of the partitioning value lists, the `INSERT` query will fail with an error. For example, given the `LIST` partitioning scheme just outlined, this query will fail:

```
INSERT INTO employees VALUES
    (224, 'Linus', 'Torvalds', '2002-05-01', '2004-10-12', 42, 21);
```

Failure occurs because the `store_id` column value `21` is not found in any of the value lists used to define partitions `pNorth`, `pEast`, `pWest`, or `pCentral`. It is important to note that there is no "catch-all" definition for list partitions analogous to `VALUES LESS THAN MAXVALUE` which accommodates values not found in any of the value lists. In other words, *any value which is to be matched must be found in one of the value lists*.

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 18.2.5, "Subpartitioning".

18.2.3. `HASH` Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (`*`expr`*`)` clause, where *`expr`* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS` *`num`* clause, where *`num`* is a non-negative integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to `1`. **Exception**: For `NDB Cluster` tables, the default number of partitions is the same as the number of cluster data nodes, possibly modified to take into account any `MAX_ROWS` setting in order to ensure that all rows can fit into the partitions. (See Chapter 17, *MySQL Cluster*.)

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *`expr`*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

You may use any function or other expression for *`expr`* that is valid in MySQL, so long as it returns a non-constant, non-random integer value. (In other words, it should be varying but deterministic.) However, you should keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for "pruning" on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from `5` to `6` produces a change of `-1` in the value of the expression, but changing the value of `int_col` from `6` to `7` produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation `y=`*`n`*`x` where *`n`* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than column value, but determining which of these are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *`num`* partitions to use based on the modulus of the result of the user function. In other words, for an expression *`expr`*, the partition in which the record is stored is partition number *`N`*, where *`N`* `= MOD(`*`expr`*`, `*`num`*`)`. For example, suppose table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
=  MOD(2005,4)
=  1
```

MySQL 5.1 also supports a variant of HASH partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 18.2.3.1, "LINEAR HASH Partitioning", for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also — depending on the circumstances — be evaluated when records are deleted.

Note: If the table to be partitioned has a UNIQUE key, then any columns supplied as arguments to the HASH user function or to the KEY's *column_list* must be part of that key.

18.2.3.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the LINEAR keyword in the PARTITION BY clause, as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LINEAR HASH(YEAR(hired))
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

   ```
   V = POWER(2, CEILING(LOG(2, num)))
   ```

   (For example, suppose that *num* is 13. Then LOG(2,13) is 3.7004397181411. CEILING(3.7004397181411) is 4, and *V* = POWER(2,4), which is 16.)

2. Set *N* = *F*(*column_list*) & (*V* - 1).

3. While *N* >= *num*:

   - Set *V* = CEIL(*V* / 2)
   - Set *N* = *N* & (*V* - 1)

For example, suppose that the table t1, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR HASH( YEAR(col3) )
    PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING(LOG(2,7))) = 8
N = YEAR('2003-04-14') & (8 - 1)
   = 2003 & 7
   = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)

N = 6 & CEILING(5 / 2)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

18.2.4. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The only differences are that you use `KEY` rather than `HASH`, and that `KEY` takes only a list of one or more column names.

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 18.2.3.1, “`LINEAR HASH` Partitioning”, for a description of this algorithm and its implications.

18.2.5. Subpartitioning

Subpartitioning — also known as *composite partitioning* — is the further division of each partition in a partitioned table. For example, consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH(TO_DAYS(purchased))
    SUBPARTITIONS 2 (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    );
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions — `p0`, `p1`, and `p2` — is further divided into 2 subpartitions. In effect, the entire table is divided into `3 * 2 = 6` partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses in order to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

  ```
  CREATE TABLE ts (id INT, purchased DATE)
      PARTITION BY RANGE( YEAR(purchased) )
      SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
          PARTITION p0 VALUES LESS THAN (1990) (
              SUBPARTITION s0,
              SUBPARTITION s1
          ),
          PARTITION p1 VALUES LESS THAN (2000),
          PARTITION p2 VALUES LESS THAN MAXVALUE (
              SUBPARTITION s2,
              SUBPARTITION s3
          )
      );
  ```

  This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each SUBPARTITION clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- Names of subpartitions must be unique within each partition, but do not have to be unique within the table as a whole. For example, the following CREATE TABLE statement is valid:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s0,
            SUBPARTITION s1
        )
    );
```

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as /disk0, /disk1, /disk2, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk0/data'
                INDEX DIRECTORY = '/disk0/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk1/data'
                INDEX DIRECTORY = '/disk1/idx'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk2/data'
                INDEX DIRECTORY = '/disk2/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk3/data'
                INDEX DIRECTORY = '/disk3/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        )
    );
```

In this case, a separate disk is used for the data and for the indexes of each RANGE. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH(TO_DAYS(purchased)) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0a
```

```
            DATA DIRECTORY = '/disk0'
            INDEX DIRECTORY = '/disk1',
        SUBPARTITION s0b
            DATA DIRECTORY = '/disk2'
            INDEX DIRECTORY = '/disk3'
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s1a
            DATA DIRECTORY = '/disk4/data'
            INDEX DIRECTORY = '/disk4/idx',
        SUBPARTITION s1b
            DATA DIRECTORY = '/disk5/data'
            INDEX DIRECTORY = '/disk5/idx'
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s2a,
        SUBPARTITION s2b
    )
);
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4` — the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5` — the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

  In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See Section 18.3, “Partition Management”, for an explanation of how this can be done.

18.2.6. How MySQL Partitioning Handles `NULL` Values

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. In general, MySQL will treat a `NULL` as a zero in such cases. If you wish to circumvent this behavior, you should design tables so as not to allow nulls; most likely you can do so by declaring columns `NOT NULL`.

In this section, we provide some examples illustrating how MySQL handles `NULL` values when determining the partition in which a row should be stored.

If you insert a row into a table partitioned by RANGE or LIST such that the column value used to determine the partition is NULL, it is treated as 0. For example, consider these two tables, created and populated as follows:

```
mysql> CREATE TABLE tnlist (
    ->     id INT,
    ->     name VARCHAR(5)
    -> )
    -> PARTITION BY LIST(id) (
    ->     PARTITION p1 VALUES IN (0),
    ->     PARTITION p2 VALUES IN (1)
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE tnrange (
    ->     id INT,
    ->     name VARCHAR(5)
    -> )
    -> PARTITION BY RANGE(id) (
    ->     PARTITION p1 VALUES LESS THAN (1),
    ->     PARTITION p2 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO tnlist VALUES (NULL, 'bob');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO tnrange VALUES (NULL, 'jim');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tnlist;
+------+------+
| id   | name |
+------+------+
| NULL | bob  |
+------+------+
1 row in set (0.00 sec)

mysql> SELECT * FROM tnrange;
+------+------+
| id   | name |
+------+------+
| NULL | jim  |
+------+------+
1 row in set (0.00 sec)
```

In both tables, the id column was not declared as NOT NULL, which means that it admits NULL values. You can verify that the rows were stored in the partitions p1 of the each table by dropping these partitions, and then re-running the SELECT statements:

```
mysql> ALTER TABLE tnlist DROP PARTITION p1;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE tnrange DROP PARTITION p1;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM tnlist;
Empty set (0.00 sec)

mysql> SELECT * FROM tnrange;
Empty set (0.00 sec)
```

In the case of partitioning by HASH or KEY, any partition expression that yields a NULL value is treated as though its return value were zero. We can verify this behavior by examining the effects on the filesystem of creating a table partitioned by HASH and populating it with a record containing appropriate values. Suppose you have a table tnhash, created in the test database, using this state-

ment:

```
CREATE TABLE tnhash (
    id INT,
    name VARCHAR(5)
)
PARTITION BY HASH(id)
PARTITIONS 2;
```

Assuming an RPM installation of MySQL on Linux, this statement creates two `.MYD` files in `/var/lib/mysql/test`, which can be viewed in the `bash` shell as follows:

```
/var/lib/mysql/test> ls *.MYD -l
-rw-rw----  1 mysql mysql 0 2005-11-04 18:41 tnhash_p0.MYD
-rw-rw----  1 mysql mysql 0 2005-11-04 18:41 tnhash_p1.MYD
```

Note that the size of each file is 0 bytes. Now insert a row into `tnhash` whose `id` column value is `NULL` and verify that this row was inserted:

```
mysql> INSERT INTO tnhash VALUES (NULL, 'sam');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tnhash;
+------+------+
| id   | name |
+------+------+
| NULL | sam  |
+------+------+
1 row in set (0.01 sec)
```

Recall that for any integer *N*, the value of `NULL MOD N` is always `NULL`. This result is treated for determining the correct partition as `0`. Returning to the system shell (still assuming `bash` for this purpose), we can see that the value was inserted into the first partition (named `p0` by default) by listing the data files once again:

```
var/lib/mysql/test> ls *.MYD -l
-rw-rw----  1 mysql mysql 20 2005-11-04 18:44 tnhash_p0.MYD
-rw-rw----  1 mysql mysql  0 2005-11-04 18:41 tnhash_p1.MYD
```

You can see that the `INSERT` statement modified only the file `tnhash_p0.MYD`, increasing its size on disk, without affecting the other data file.

Suppose we have a table such as this one:

```
CREATE TABLE tndate (
    id INT,
    dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to `0`, and is inserted into partition `p0`.

18.3. Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partition-

ing extensions to the ALTER TABLE command (see Section 13.1.2, "ALTER TABLE Syntax", for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by RANGE or LIST, see Section 18.3.1, "Management of RANGE and LIST Partitions".
- For a discussion of managing HASH and KEY partitions, see Section 18.3.2, "Management of HASH and KEY Partitions".
- See Section 18.3.4, "Obtaining Information About Partitions", for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see Section 18.3.3, "Maintenance of Partitions".

Note: In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

Important: Currently, ALTER TABLE ... PARTITION BY ... is accepted as valid syntax by a MySQL server built from the 5.1 tree, but the statement actually does nothing. We expect to implement the behavior of this statement as described below by the time that MySQL 5.1 reaches production status.

To change a table's partitioning scheme, it is necessary only to use the ALTER TABLE command with a *partition_options* clause. This clause has the same syntax as that as used with CREATE TABLE for creating a partitioned table, and always begins with the keywords PARTITION BY. For example, suppose you have a table partitioned by range using the following CREATE TABLE statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    );
```

To repartition this table so that it is partitioned by key into two partitions using the id column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;.

18.3.1. Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 18.3.2, "Management of HASH and KEY Partitions". Dropping a RANGE or LIST partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either RANGE or by LIST can be accomplished using the ALTER TABLE command with a DROP PARTITION clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following CREATE TABLE and INSERT statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
```

```
    ->     PARTITION BY RANGE( YEAR(purchased) ) (
    ->         PARTITION p0 VALUES LESS THAN (1990),
    ->         PARTITION p1 VALUES LESS THAN (1995),
    ->         PARTITION p2 VALUES LESS THAN (2000),
    ->         PARTITION p3 VALUES LESS THAN (2005)
    ->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
    ->     (1, 'desk organiser', '2003-10-15'),
    ->     (2, 'CD player', '1993-11-05'),
    ->     (3, 'TV set', '1996-03-10'),
    ->     (4, 'bookcase', '1982-01-10'),
    ->     (5, 'exercise bike', '2004-05-09'),
    ->     (6, 'sofa', '1987-06-05'),
    ->     (7, 'popcorn maker', '2001-11-22'),
    ->     (8, 'aquarium', '1992-08-04'),
    ->     (9, 'study desk', '1984-09-16'),
    ->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
    -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-----------+------------+
| id   | name      | purchased  |
+------+-----------+------------+
|    3 | TV set    | 1996-03-10 |
|   10 | lava lamp | 1998-12-25 |
+------+-----------+------------+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` command. (See Section 13.2.9, "`TRUNCATE` Syntax".)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in Section 13.1.2, "`ALTER TABLE` Syntax", for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` command, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
       Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

```
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
+------+---------------+------------+
| id   | name          | purchased  |
+------+---------------+------------+
|   11 | pencil holder | 1995-07-12 |
|    1 | desk organiser | 2003-10-15 |
|    5 | exercise bike | 2004-05-09 |
|    7 | popcorn maker | 2001-11-22 |
+------+---------------+------------+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as use for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterwards: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See Section 18.2.2, "`LIST` Partitioning", for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the beginning or end of the list of existing partitions. For example, suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```
CREATE TABLE members (
    id INT,
    fname VARCHAR(25),
    lname VARCHAR(25),
    dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION p0 VALUES LESS THAN (1970),
    PARTITION p1 VALUES LESS THAN (1980),
    PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990-1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

Important: With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
    >     ADD PARTITION (
    >     PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly increasing for each
```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```
CREATE TABLE tt (
    id INT,
    data INT
)
PARTITION BY LIST(data) (
    PARTITION p0 VALUES IN (5, 10, 15),
    PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
    >     (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. In order to accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1` — and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
       Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
```

```
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM.
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` in order to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, *`tbl_name`* is the name of the partitioned table, and *`partition_list`* is a comma-separated list of names of one or more existing partitions to be changed. *`partition_definitions`* is a comma-separated list of new partition definitions, which follow the same rules as for the *`partition_definitions`* list used in `CREATE TABLE` (see Section 13.1.5, “`CREATE TABLE` Syntax”). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only non-conflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

  Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

  Note: Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See Section D.1.2, "Changes in release 5.1.4 (21 December 2005)", for more information.

- The combination of partitions in the *`partition_definitions`* list should account for the same range or set of values overall as the combined partitions named in the *`partition_list`*.

  For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

  For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

  ```
  ALTER TABLE members
      PARTITION BY HASH(YEAR(dob))
      PARTITIONS 8;
  ```

  Note: In MySQL 5.1 5.1.5-alpha, `ALTER TABLE ... PARTITION BY ...` is not yet implemented. Instead, you must either drop and re-create the table using the desired partitioning, or — if you need to retain data already stored in the table — you can use `CREATE TABLE ... SELECT ...` to create the new table and copy the data from the old one, and then drop the old table, renaming the new one as a final step if desired.

18.3.2. Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 18.3.1, "Management of `RANGE` and `LIST` Partitions".

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` command. For example, sup-

pose you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
    id INT,
    fname VARCHAR(30),
    lname VARCHAR(30),
    signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to six, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 6;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
    ->     id INT,
    ->     fname VARCHAR(30),
    ->     lname VARCHAR(30),
    ->     signed DATE
    -> )
    -> PARTITION BY LINEAR KEY(signed)
    -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 6;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

`COALESCE` cannot be used to increase the number of partitions, and if you attempt to do so, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18. use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 18;
```

Note: `ALTER TABLE ... REORGANIZE PARTITION` cannot be used with tables that are partitioned by `HASH` or `KEY`.

18.3.3. Maintenance of Partitions

Note: The commands discussed in this section are not yet actually implemented in MySQL 5.1 and are presented for purposes of eliciting feedback from users testing the software during the 5.1 preproduction development cycle. (In other words, “Please do not file bugs saying that these commands do not work”.) This information is highly subject to change as MySQL 5.1 partitioning development continues. We will update this section as our partitioning features are implemented and improved.

A number of partitioning maintenance tasks can be carried out in MySQL 5.1. MySQL does not support the commands `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, or `REPAIR TABLE` for partitioned tables. Instead, you can use a number of extensions to `ALTER TABLE` can

be used for performing these operations on one or more partitions directly, as described in the following list:

- **Rebuilding partitions**: Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```
  ALTER TABLE t1 REBUILD PARTITION (p0, p1);
  ```

- **Optimizing partitions**: If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

  Example:

  ```
  ALTER TABLE t1 OPTIMIZE PARTITION (p0, p1);
  ```

  Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions**: This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION (p3);
  ```

- **Repairing partitions**: This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION (p0,p1);
  ```

- **Checking partitions**: You can check partitions for errors in much the same way that you can use `CHECK TABLE` with non-partitioned tables.

  Example:

  ```
  ALTER TABLE trb3 CHECK PARTITION (p1);
  ```

  This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

You can also use the `mysqlcheck` or `myisamchk` utility to accomplish these tasks, operating on the separate `.MYI` files generated by partitioning a table. See Section 8.7, “mysqlcheck — A Table Maintenance and Repair Program”. (This is already available in the pre-alpha code.)

18.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions. This functionality is still in the planning stages, so what is described here actually at this time serves as a survey of what we intend to implement in MySQL 5.1.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
```

```
*************************** 1. row ***************************
       Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

Note: Currently the `PARTITIONS` clause is not shown for tables partitioned by `HASH` or `KEY`. (Bug #14327 [http://bugs.mysql.com/14327])

`SHOW TABLE STATUS` works with partitioned tables, and its output is the same as that for non-partitioned tables, except that the `Engine` column always contains the value `'PARTITION'`. (See Section 13.5.4.18, "`SHOW TABLE STATUS` Syntax", for more information about this command.) To obtain status information for individual partitions, we plan to implement a `SHOW PARTITION STATUS` command (see below).

Two additional `SHOW` commands are planned for use with partitioned tables:

- `SHOW PARTITIONS`

  This command is expected to work similarly to `SHOW TABLES` and `SHOW DATABASES`, except that it will list partitions rather than tables or databases. The output from this command will likely consist of a single column named `Partitions_in_`*`tbl_name`*, where *`tbl_name`* is the name of the partitioned table. Since it is not possible to "select" a table in the sense that one selects a database and it thereafter serves as the default database for `SHOW TABLES`, it is likely that `SHOW PARTITIONS` will require the use of a `FROM` clause so that MySQL knows which table is intended.

- `SHOW PARTITION STATUS`

  This command will provide detailed status information about one or more partitions. Its output will likely contain the same columns as or columns similar to those found in the output of `SHOW TABLE STATUS`, with the addition of columns showing the data and index directories used for the partition. This command is likely to support `LIKE` and `FROM` clauses that will make it possible to obtain information about a given partition by name, or about partitions belonging to specific table or database.

Planning is also underway to augment the `INFORMATION_SCHEMA` database to provide information about partitioned tables and partitions. This planning is currently in a very early phase; we will update the relevant portions of the Manual as additional information becomes available and any new partitioning-related extensions to `INFORMATION_SCHEMA` are implemented.

Chapter 19. Spatial Extensions in MySQL

MySQL supports spatial extensions to allow the generation, storage, and analysis of geographic features. These features are available for `MyISAM`, `InnoDB`, `NDB`, `BDB`, and `ARCHIVE` tables. (However, the `ARCHIVE` engine does not support indexing, so spatial columns in `ARCHIVE` columns cannot be indexed. MySQL Cluster also does not support indexing of spatial columns.)

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

Additional resources

- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss these in the GIS forums: http://forums.mysql.com/list.php?23.

19.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the `Open GIS Consortium` (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at http://www.opengis.org/.

In 1997, the Open GIS Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the Open GIS Web site at http://www.opengis.org/docs/99-049.pdf. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specifications describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, a postcode area, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

You can also find documents that use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used here is **geometry**.

Let's define a **geometry** as *a point or an aggregate of points representing anything in the world that has a location*.

19.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

19.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (non-instantiable)
  - `Point` (instantiable)
  - `Curve` (non-instantiable)
    - `LineString` (instantiable)
      - `Line`
      - `LinearRing`
  - `Surface` (non-instantiable)
    - `Polygon` (instantiable)
  - `GeometryCollection` (instantiable)
    - `MultiPoint` (instantiable)
    - `MultiCurve` (non-instantiable)
      - `MultiLineString` (instantiable)
    - `MultiSurface` (non-instantiable)
      - `MultiPolygon` (instantiable)

It is not possible to create objects in non-instantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It's an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional co-

ordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with subsubclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

19.2.2. Class `Geometry`

`Geometry` is the root class of the hierarchy. It is a non-instantiable class but has a number of properties that are common to all geometry values created from any of the `Geometry` subclasses. These properties are described in the following list. (Particular subclasses have their own specific properties, described later.)

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

  In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.
- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

  Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.
- Its **interior**, **boundary**, and **exterior**.

  Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.
- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed

by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types (`LineString`, `MultiPoint`, `MultiLineString`) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types (`LineString`, `MultiString`) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **non-empty** A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a `NULL` value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of #1, 0, 1, or 2:
  - #1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with non-zero length and zero area.
  - 2 for a geometry with non-zero area.

  `Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

19.2.3. Class `Point`

A `Point` is a geometry that represents a single location in coordinate space.

`Point` Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

`Point` Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

19.2.4. Class `Curve`

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a non-instantiable class.

`Curve` Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice.
- A `Curve` is closed if its start point is equal to its end point.
- The boundary of a closed `Curve` is empty.
- The boundary of a non-closed `Curve` consists of its two end points.
- A `Curve` that is simple and closed is a `LinearRing`.

19.2.5. Class `LineString`

A `LineString` is a `Curve` with linear interpolation between points.

`LineString` Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

`LineString` Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

19.2.6. Class `Surface`

A `Surface` is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is `Polygon`.

`Surface` Properties

- A `Surface` is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple `Surface` as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple `Surface` is the set of closed curves corresponding to its exterior and interior boundaries.

19.2.7. Class `Polygon`

A `Polygon` is a planar `Surface` representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the `Polygon`.

`Polygon` Examples

- On a region map, `Polygon` objects could represent forests, districts, an so on.

`Polygon` Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.
- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

19.2.8. Class `GeometryCollection`

A `GeometryCollection` is a geometry that is a collection of one or more geometries of any class.

All the elements in a `GeometryCollection` must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a `GeometryCollection`, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

19.2.9. Class `MultiPoint`

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

`MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

`MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).

- The boundary of a `MultiPoint` is the empty set.

19.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a non-instantiable class.

`MultiCurve` Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the "mod 2 union rule" (also known as the "odd-even rule"): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

19.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

`MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

19.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a non-instantiable class. Its only instantiable subclass is `MultiPolygon`.

`MultiSurface` Assertions

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

19.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

`MultiPolygon` Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

`MultiPolygon` Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

`MultiPolygon` Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

19.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

19.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects are:

- A `Point`:

  ```
  POINT(15 20)
  ```

  Note that point coordinates are specified with no separating comma.

- A `LineString` with four points:

  ```
  LINESTRING(0 0, 10 10, 20 25, 50 60)
  ```

  Note that point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:

  ```
  POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
  ```

- A `MultiPoint` with three `Point` values:

  ```
  MULTIPOINT(0 0, 20 20, 60 60)
  ```

- A `MultiLineString` with two `LineString` values:

  ```
  MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
  ```

- A `MultiPolygon` with two `Polygon` values:

  ```
  MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
  ```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

  ```
  GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
  ```

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OGC specification document referenced near the beginning of this chapter.

19.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specifications. It is also defined in the ISO "SQL/MM Part 3: Spatial" standard.

WKB is used to exchange geometry data as binary streams represented by `BLOB` values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
0101000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 000000000000F03F
Y          : 000000000000F03F
```

Component representation is as follows:

- The byte order may be either 0 or 1 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.

- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

19.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

19.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINESTRING`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types, `POINT` and `LINESTRING` and `POLYGON`, restrict their values to a particular geometry type.

The other data types hold collections of values:

- `MULTIPOINT`
- `MULTILINESTRING`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types, `MULTIPOINT` and `MULTILINESTRING` and `MULTIPOLYGON` and `GEOMETRYCOLLECTION`, restrict collection members to those having a particular geometry type.

19.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

19.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid])`, `GeometryCollectionFromText(wkt[,srid])`

  Constructs a `GEOMETRYCOLLECTION` value using its WKT representation and SRID.

- `GeomFromText(wkt[,srid])`, `GeometryFromText(wkt[,srid])`

  Constructs a geometry value of any type using its WKT representation and SRID.

- `LineFromText(wkt[,srid])`, `LineStringFromText(wkt[,srid])`

  Constructs a `LINESTRING` value using its WKT representation and SRID.

- `MLineFromText(wkt[,srid])`, `MultiLineStringFromText(wkt[,srid])`

  Constructs a `MULTILINESTRING` value using its WKT representation and SRID.

- `MPointFromText(wkt[,srid])`, `MultiPointFromText(wkt[,srid])`

  Constructs a `MULTIPOINT` value using its WKT representation and SRID.

- `MPolyFromText(wkt[,srid])`, `MultiPolygonFromText(wkt[,srid])`

  Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.

- `PointFromText(wkt[,srid])`

  Constructs a `POINT` value using its WKT representation and SRID.

- `PolyFromText(wkt[,srid])`, `PolygonFromText(wkt[,srid])`

  Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromText(wkt,srid)`

  Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromText(wkt,srid)`

  Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

19.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid])`, `GeometryCollectionFromWKB(wkb[,srid])`

Constructs a GEOMETRYCOLLECTION value using its WKB representation and SRID.

- GeomFromWKB(*wkb*[,*srid*]), GeometryFromWKB(*wkb*[,*srid*])

  Constructs a geometry value of any type using its WKB representation and SRID.

- LineFromWKB(*wkb*[,*srid*]), LineStringFromWKB(*wkb*[,*srid*])

  Constructs a LINESTRING value using its WKB representation and SRID.

- MLineFromWKB(*wkb*[,*srid*]), MultiLineStringFromWKB(*wkb*[,*srid*])

  Constructs a MULTILINESTRING value using its WKB representation and SRID.

- MPointFromWKB(*wkb*[,*srid*]), MultiPointFromWKB(*wkb*[,*srid*])

  Constructs a MULTIPOINT value using its WKB representation and SRID.

- MPolyFromWKB(*wkb*[,*srid*]), MultiPolygonFromWKB(*wkb*[,*srid*])

  Constructs a MULTIPOLYGON value using its WKB representation and SRID.

- PointFromWKB(*wkb*[,*srid*])

  Constructs a POINT value using its WKB representation and SRID.

- PolyFromWKB(*wkb*[,*srid*]), PolygonFromWKB(*wkb*[,*srid*])

  Constructs a POLYGON value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing Polygon or MultiPolygon values based on the WKB representation of a collection of rings or closed LineString values. These values may intersect. MySQL does not implement these functions:

- BdMPolyFromWKB(*wkb*,*srid*)

  Constructs a MultiPolygon value from a MultiLineString value in WKB format containing an arbitrary collection of closed LineString values.

- BdPolyFromWKB(*wkb*,*srid*)

  Constructs a Polygon value from a MultiLineString value in WKB format containing an arbitrary collection of closed LineString values.

19.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specifications. The results of these functions are BLOB values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the GeomFromWKB() function family.

- GeometryCollection(*g1*,*g2*,...)

  Constructs a WKB GeometryCollection. If any argument is not a well-formed WKB representation of a geometry, the return value is NULL.

- LineString(*pt1*,*pt2*,...)

Constructs a WKB `LineString` value from a number of WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`. If the number of `Point` arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls1,ls2,...)`

  Constructs a WKB `MultiLineString` value using WKB `LineString` arguments. If any argument is not a WKB `LineString`, the return value is `NULL`.

- `MultiPoint(pt1,pt2,...)`

  Constructs a WKB `MultiPoint` value using WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`.

- `MultiPolygon(poly1,poly2,...)`

  Constructs a WKB `MultiPolygon` value from a set of WKB `Polygon` arguments. If any argument is not a WKB `Polygon`, the return value is `NULL`.

- `Point(x,y)`

  Constructs a WKB `Point` using its coordinates.

- `Polygon(ls1,ls2,...)`

  Constructs a WKB `Polygon` value from a number of WKB `LineString` arguments. If any argument does not represent the WKB of a `LinearRing` (that is, not a closed and simple `LineString`) the return value is `NULL`.

19.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, `BDB`, and `ARCHIVE` tables. See also the annotations about spatial indexes under Section 19.6.1, “Creating Spatial Indexes”.

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
mysql> CREATE TABLE geom (g GEOMETRY);
Query OK, 0 rows affected (0.02 sec)
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
mysql> ALTER TABLE geom ADD pt POINT;
Query OK, 0 rows affected (0.00 sec)
Records: 0  Duplicates: 0  Warnings: 0
mysql> ALTER TABLE geom DROP pt;
Query OK, 0 rows affected (0.00 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

19.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format.

You can perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

Or you can perform the conversion prior to the `INSERT`:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use `GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

  ```
  mysql> INSERT INTO geom VALUES
      -> (GeomFromWKB(0x0101000000000000000000F03F000000000000F03F));
  ```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

  ```
  INSERT INTO geom VALUES (GeomFromWKB(?))
  ```

  Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See Section 25.2.3.52, “`mysql_real_escape_string()`”.

19.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

19.4.5.1. Fetching Spatial Data in Internal Format

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

19.4.5.2. Fetching Spatial Data in WKT Format

The `AsText()` function converts a geometry from internal format into a WKT string.

```
SELECT AsText(g) FROM geom;
```

19.4.5.3. Fetching Spatial Data in WKB Format

The `AsBinary()` function converts a geometry from internal format into a `BLOB` containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

19.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as `mysql` or `MySQLCC`
- Application programs written in any language that supports a MySQL client API

19.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(`*g*`)`

  Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g)`

  Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+--------------------------+
| AsText(GeomFromText(@g)) |
+--------------------------+
| LINESTRING(1 1,2 2,3 3)  |
+--------------------------+
```

- `GeomFromText(wkt[,srid])`

  Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` and `LineFromText()`; see Section 19.4.2.1, “Creating Geometry Values Using WKT Functions”.

- `GeomFromWKB(wkb[,srid])`

  Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` and `LineFromWKB()`; see Section 19.4.2.2, “Creating Geometry Values Using WKB Functions”.

19.5.2. `Geometry` Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, `Area()` returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

19.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

  Returns the inherent dimension of the geometry value *g*. The result can be #1, 0, 1, or 2. (The meaning of these values is given in Section 19.2.2, “Class `Geometry`”.)

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+---------------------------------------------+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+---------------------------------------------+
|                                           1 |
+---------------------------------------------+
```

- `Envelope(g)`

  Returns the Minimum Bounding Rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----------------------------------------------------+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----------------------------------------------------+
| POLYGON((1 1,2 1,2 2,1 2,1 1))                      |
+-----------------------------------------------------+
```

- `GeometryType(`*g*`)`

  Returns as a string the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----------------------------------------+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----------------------------------------+
| POINT                                   |
+-----------------------------------------+
```

- `SRID(`*g*`)`

  Returns an integer indicating the Spatial Reference System ID for the geometry value *g*.

  In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----------------------------------------------+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----------------------------------------------+
|                                           101 |
+-----------------------------------------------+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Boundary(`*g*`)`

  Returns a geometry that is the closure of the combinatorial boundary of the geometry value *g*.

- `IsEmpty(`*g*`)`

  Returns 1 if the geometry value *g* is the empty geometry, 0 if it is not empty, and #1 if the argument is `NULL`. If the geometry is empty, it represents the empty point set.

- `IsSimple(`*g*`)`

  Currently, this function is a placeholder and should not be used. If implemented, its behavior will be as described in the next paragraph.

  Returns 1 if the geometry value *g* has no anomalous geometric points, such as self-intersection or self-tangency. `IsSimple()` returns 0 if the argument is not simple, and #1 if it is `NULL`.

  The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple.

19.5.2.2. `Point` Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- `X(`*`p`*`)`

  Returns the X-coordinate value for the point *`p`* as a double-precision number.

```
mysql> SELECT X(GeomFromText('Point(56.7 53.34)'));
+-------------------------------------+
| X(GeomFromText('Point(56.7 53.34)')) |
+-------------------------------------+
|                                56.7 |
+-------------------------------------+
```

- `Y(`*`p`*`)`

  Returns the Y-coordinate value for the point *`p`* as a double-precision number.

```
mysql> SELECT Y(GeomFromText('Point(56.7 53.34)'));
+-------------------------------------+
| Y(GeomFromText('Point(56.7 53.34)')) |
+-------------------------------------+
|                               53.34 |
+-------------------------------------+
```

19.5.2.3. `LineString` Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- `EndPoint(`*`ls`*`)`

  Returns the `Point` that is the end point of the `LineString` value *`ls`*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-------------------------------------+
| AsText(EndPoint(GeomFromText(@ls))) |
+-------------------------------------+
| POINT(3 3)                          |
+-------------------------------------+
```

- `GLength(`*`ls`*`)`

  Returns as a double-precision number the length of the `LineString` value *`ls`* in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+---------------------------+
| GLength(GeomFromText(@ls)) |
+---------------------------+
|           2.8284271247462 |
+---------------------------+
```

- `NumPoints(`*`ls`*`)`

  Returns the number of points in the `LineString` value *`ls`*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----------------------------+
| NumPoints(GeomFromText(@ls)) |
+-----------------------------+
|                           3 |
+-----------------------------+
```

- `PointN(ls,n)`

  Returns the *n*-th point in the `Linestring` value *ls*. Point numbers begin at 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-------------------------------------+
| AsText(PointN(GeomFromText(@ls),2)) |
+-------------------------------------+
| POINT(2 2)                          |
+-------------------------------------+
```

- `StartPoint(ls)`

  Returns the `Point` that is the start point of the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+---------------------------------------+
| AsText(StartPoint(GeomFromText(@ls))) |
+---------------------------------------+
| POINT(1 1)                            |
+---------------------------------------+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)`

  Returns 1 if the `LineString` value *ls* is closed (that is, its `StartPoint()` and `EndPoint()` values are the same) and is simple (does not pass through the same point more than once). Returns 0 if *ls* is not a ring, and #1 if it is `NULL`.

19.5.2.4. `MultiLineString` Functions

- `GLength(mls)`

  Returns as a double-precision number the length of the `MultiLineString` value *mls*. The length of *mls* is equal to the sum of the lengths of its elements.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----------------------------+
| GLength(GeomFromText(@mls)) |
+-----------------------------+
|             4.2426406871193 |
+-----------------------------+
```

- `IsClosed(mls)`

  Returns 1 if the `MultiLineString` value *mls* is closed (that is, the `StartPoint()` and

`EndPoint()` values are the same for each `LineString` in *`mls`*). Returns 0 if *`mls`* is not closed, and #1 if it is `NULL`.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mls));
+-----------------------------+
| IsClosed(GeomFromText(@mls)) |
+-----------------------------+
|                           0 |
+-----------------------------+
```

19.5.2.5. Polygon Functions

- `Area(`*`poly`*`)`

  Returns as a double-precision number the area of the `Polygon` value *`poly`*, as measured in its spatial reference system.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
  mysql> SELECT Area(GeomFromText(@poly));
  +---------------------------+
  | Area(GeomFromText(@poly)) |
  +---------------------------+
  |                         4 |
  +---------------------------+
  ```

- `ExteriorRing(`*`poly`*`)`

  Returns the exterior ring of the `Polygon` value *`poly`* as a `LineString`.

  ```
  mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
  +-------------------------------------------+
  | AsText(ExteriorRing(GeomFromText(@poly))) |
  +-------------------------------------------+
  | LINESTRING(0 0,0 3,3 3,3 0,0 0)           |
  +-------------------------------------------+
  ```

- `InteriorRingN(`*`poly`*`,`*`n`*`)`

  Returns the *`n`*-th interior ring for the `Polygon` value *`poly`* as a `LineString`. Ring numbers begin at 1.

  ```
  mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
  +---------------------------------------------+
  | AsText(InteriorRingN(GeomFromText(@poly),1)) |
  +---------------------------------------------+
  | LINESTRING(1 1,1 2,2 2,2 1,1 1)             |
  +---------------------------------------------+
  ```

- `NumInteriorRings(`*`poly`*`)`

  Returns the number of interior rings in the `Polygon` value *`poly`*.

  ```
  mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT NumInteriorRings(GeomFromText(@poly));
  +--------------------------------------+
  ```

```
| NumInteriorRings(GeomFromText(@poly)) |
+---------------------------------------+
|                                     1 |
+---------------------------------------+
```

19.5.2.6. MultiPolygon Functions

- Area(*mpoly*)

  Returns as a double-precision number the area of the MultiPolygon value *mpoly*, as measured in its spatial reference system.

```
mysql> SET @mpoly =
    -> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+----------------------------+
| Area(GeomFromText(@mpoly)) |
+----------------------------+
|                          8 |
+----------------------------+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- Centroid(*mpoly*)

  Returns the mathematical centroid for the MultiPolygon value *mpoly* as a Point. The result is not guaranteed to be on the MultiPolygon.

- PointOnSurface(*mpoly*)

  Returns a Point value that is guaranteed to be on the MultiPolygon value *mpoly*.

19.5.2.7. GeometryCollection Functions

- GeometryN(*gc*,*n*)

  Returns the *n*-th geometry in the GeometryCollection value *gc*. Geometry numbers begin at 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+---------------------------------------+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+---------------------------------------+
| POINT(1 1)                            |
+---------------------------------------+
```

- NumGeometries(*gc*)

  Returns the number of geometries in the GeometryCollection value *gc*.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+---------------------------------+
| NumGeometries(GeomFromText(@gc)) |
+---------------------------------+
```

```
|                                  2 |
+------------------------------------+
```

19.5.3. Functions That Create New Geometries from Existing Ones

19.5.3.1. Geometry Functions That Produce New Geometries

In the section Section 19.5.2, "`Geometry` Functions", we've discussed some functions that can construct new geometries from the existing ones:

- `Envelope(`*`g`*`)`
- `StartPoint(`*`ls`*`)`
- `EndPoint(`*`ls`*`)`
- `PointN(`*`ls`*`,`*`n`*`)`
- `ExteriorRing(`*`poly`*`)`
- `InteriorRingN(`*`poly`*`,`*`n`*`)`
- `GeometryN(`*`gc`*`,`*`n`*`)`

19.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- `Buffer(`*`g`*`,`*`d`*`)`

  Returns a geometry that represents all points whose distance from the geometry value *`g`* is less than or equal to a distance of *`d`*.

- `ConvexHull(`*`g`*`)`

  Returns a geometry that represents the convex hull of the geometry value *`g`*.

- `Difference(`*`g1`*`,`*`g2`*`)`

  Returns a geometry that represents the point set difference of the geometry value *`g1`* with *`g2`*.

- `Intersection(`*`g1`*`,`*`g2`*`)`

  Returns a geometry that represents the point set intersection of the geometry values *`g1`* with *`g2`*.

- `SymDifference(`*`g1`*`,`*`g2`*`)`

  Returns a geometry that represents the point set symmetric difference of the geometry value *`g1`* with *`g2`*.

- `Union(`*`g1`*`,`*`g2`*`)`

  Returns a geometry that represents the point set union of the geometry values *`g1`* and *`g2`*.

19.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

19.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides some functions that can test relations between minimal bounding rectangles of two geometries `g1` and `g2`. They include:

- `MBRContains(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangle of *`g1`* contains the Minimum Bounding Rectangle of *`g2`*.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
----------------------+----------------------+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+----------------------+----------------------+
|                    1 |                    0 |
+----------------------+----------------------+
```

- `MBRDisjoint(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries *`g1`* and *`g2`* are disjoint (do not intersect).

- `MBREqual(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries *`g1`* and *`g2`* are the same.

- `MBRIntersects(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries *`g1`* and *`g2`* intersect.

- `MBROverlaps(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries *`g1`* and *`g2`* overlap.

- `MBRTouches(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries *`g1`* and *`g2`* touch.

- `MBRWithin(`*`g1`*`,`*`g2`*`)`

  Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangle of *`g1`* is within the Minimum Bounding Rectangle of *`g2`*.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-------------------+-------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
```

```
+--------------------+--------------------+
|                  1 |                  0 |
+--------------------+--------------------+
```

19.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. Currently, MySQL does not implement them according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than `Distance()` and `Related()`.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

The functions operate on two geometry values `g1` and `g2`.

- `Contains(g1,g2)`

  Returns 1 or 0 to indicate whether or not *`g1`* completely contains *`g2`*.

- `Crosses(g1,g2)`

  Returns 1 if *`g1`* spatially crosses *`g2`*. Returns `NULL` if `g1` is a `Polygon` or a `MultiPolygon`, or if *`g2`* is a `Point` or a `MultiPoint`. Otherwise, returns 0.

  The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

  - The two geometries intersect
  - Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
  - Their intersection is not equal to either of the two given geometries

- `Disjoint(g1,g2)`

  Returns 1 or 0 to indicate whether or not *`g1`* is spatially disjoint from (does not intersect) *`g2`*.

- `Distance(g1,g2)`

  Returns as a double-precision number the shortest distance between any two points in the two geometries.

- `Equals(g1,g2)`

  Returns 1 or 0 to indicate whether or not *`g1`* is spatially equal to *`g2`*.

- `Intersects(g1,g2)`

  Returns 1 or 0 to indicate whether or not *`g1`* spatially intersects *`g2`*.

- `Overlaps(g1,g2)`

  Returns 1 or 0 to indicate whether or not *`g1`* spatially overlaps *`g2`*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- `Related(g1,g2,pattern_matrix)`

Returns 1 or 0 to indicate whether or not the spatial relationship specified by *pattern_matrix* exists between *g1* and *g2*. Returns #1 if the arguments are NULL. The pattern matrix is a string. Its specification will be noted here if this function is implemented.

- Touches(*g1*,*g2*)

  Returns 1 or 0 to indicate whether or not *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- Within(*g1*,*g2*)

  Returns 1 or 0 to indicate whether or not *g1* is spatially within *g2*.

19.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** to index spatial columns. A spatial index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. You are required to declare a prefix for any (non-spatial) index on a spatial column excepting POINT columns.

19.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the SPATIAL keyword. Spatial columns that are indexed currently must be declared NOT NULL. The following examples demonstrate how to create spatial indexes.

- With CREATE TABLE:

  ```
  mysql> CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
  ```

- With ALTER TABLE:

  ```
  mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
  ```

- With CREATE INDEX:

  ```
  mysql> CREATE SPATIAL INDEX sp_index ON geom (g);
  ```

For MyISAM tables, SPATIAL INDEX creates an R-tree index. For other storage engines that support spatial index, SPATIAL INDEX creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
mysql> ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
mysql> DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-------+----------+------+-----+---------+----------------+
| Field | Type     | Null | Key | Default | Extra          |
+-------+----------+------+-----+---------+----------------+
| fid   | int(11)  |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                |
+-------+----------+------+-----+---------+----------------+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+----------+
| count(*) |
+----------+
|    32376 |
+----------+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376  Duplicates: 0  Warnings: 0
```

19.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. For example, let's say we want to find all objects that are in the given rectangle:

```
mysql> SELECT fid,AsText(g) FROM geom WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-----+-------------------------------------------------------------------------
| fid | AsText(g)
+-----+-------------------------------------------------------------------------
|  21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30333.8 15828.8)
|  22 | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8,30334 15871.4)
|  23 | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4,30334 15914.2)
|  24 | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4,30273.4 15823)
|  25 | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882.4,30274.8 1586
|  26 | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4,30275 15918.2)
| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946.8,30320.4 1593
|   1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136.4,30240 15127.
|   2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136,30210.4 15121)

| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30259 15083.4)
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4,30128.8 15001)
+-----+-------------------------------------------------------------------
20 rows in set (0.00 sec)
```

Let's use `EXPLAIN` to check the way this query is executed (the `id` column has been removed so the output better fits the page):

```
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-------------+-------+-------+---------------+------+---------+------+------+-
| select_type | table | type  | possible_keys | key  | key_len | ref  | rows | 
+-------------+-------+-------+---------------+------+---------+------+------+-
| SIMPLE      | geom  | range | g             | g    |      32 | NULL |   50 | 
+-------------+-------+-------+---------------+------+---------+------+------+-
1 row in set (0.00 sec)
```

Let's check what would happen without a spatial index:

```
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-------------+-------+------+---------------+------+---------+------+-------+-
| select_type | table | type | possible_keys | key  | key_len | ref  | rows  | 
+-------------+-------+------+---------------+------+---------+------+-------+-
| SIMPLE      | geom  | ALL  | NULL          | NULL |    NULL | NULL | 32376 | 
+-------------+-------+------+---------------+------+---------+------+-------+-
1 row in set (0.00 sec)
```

Let's execute the `SELECT` statement, ignoring the spatial key we have:

```
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-----+--------------------------------------------------------------------
| fid | AsText(g)
+-----+--------------------------------------------------------------------
|   1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136.4,30240 15127.
|   2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136,30210.4 15121)

+-----+--------------------------------------------------------------------
20 rows in set (0.46 sec)
```

When the index is not used, the execution time for this query rises from 0.00 seconds to 0.46 seconds.

In future releases, spatial indexes may also be used for optimizing other functions. See Section 19.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”.

19.7. MySQL Conformance and Compatibility

19.7.1. GIS Features That Are Not Yet Implemented

- Additional Metadata Views

  OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`

  The problem is that there is an existing SQL function `Length()` which calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

Chapter 20. Stored Procedures and Functions

Stored procedures and functions are supported in MySQL version 5.1. A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Some situations where stored procedures can be particularly useful:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Stored procedures can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server system because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored procedures also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally, for example, by using classes. Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored procedures, which is also used by IBM's DB2.

The MySQL implementation of stored procedures is still in progress. All syntax described in this chapter is supported and any limitations and extensions are documented where appropriate. Further discussion of restrictions on use of stored procedures is given in Appendix I, *Feature Restrictions*.

Binary logging for stored routines takes place as described in Section 20.4, “Binary Logging of Stored Routines and Triggers”.

20.1. Stored Procedures and the Grant Tables

Stored procedures require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 2.10.2, “Upgrading the Grant Tables”.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

In MySQL 5.1, the grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine. Also, the default `SQL SECURITY` characteristic

for a routine is DEFINER, which allows users who have access to the database with which the routine is associated to execute the routine.

20.2. Stored Procedure Syntax

Stored procedures and functions are routines that are created with CREATE PROCEDURE and CREATE FUNCTION statements. A routine is either a procedure or a function. A procedure is invoked using a CALL statement, and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. Stored routines may call other stored routines.

In MySQL 5.1, a stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit USE *db_name* is performed (and undone when the routine terminates). USE statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure p or function f that is associated with the test database, you can say CALL test.p() or test.f().
- When a database is dropped, all stored routines associated with it are dropped as well.

MySQL supports the very useful extension that allows the use of regular SELECT statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple SELECT statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1.

The following sections describe the syntax used to create, alter, drop, and query stored procedures and functions.

20.2.1. CREATE PROCEDURE and CREATE FUNCTION

```
CREATE PROCEDURE sp_name ([proc_parameter[,...]])
    [characteristic ...] routine_body

CREATE FUNCTION sp_name ([func_parameter[,...]])
    RETURNS type
    [characteristic ...] routine_body

proc_parameter:
    [ IN | OUT | INOUT ] param_name type

func_parameter:
    param_name type

type:
    Any valid MySQL data type

characteristic:
    LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'

routine_body:
    Valid SQL procedure statement
```

These statements create stored routines. To create a routine in MySQL 5.1, it is necessary to have the CREATE ROUTINE privilege, and the ALTER ROUTINE and EXECUTE privileges are granted automatically to its creator. If binary logging is enabled, you may also need the SUPER privilege, as described in Section 20.4, “Binary Logging of Stored Routines and Triggers”.

By default, the routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as *db_name.sp_name* when you create it.

If the routine name is the same as the name of a built-in SQL function, you need to use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason — even though it is possible to do so — we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Each parameter is an IN parameter by default. To specify otherwise for a parameter, use the keyword OUT or INOUT before the parameter name.

Note: Specifying a parameter as IN, OUT, or INOUT is valid only for a PROCEDURE. (FUNCTION parameters are always regarded as IN parameters.)

The RETURNS clause may be specified only for a FUNCTION, for which it is mandatory. It is used to indicate the return type of the function, and the function body must contain a RETURN *value* statement.

The *routine_body* consists of a valid SQL procedure statement. This can be a simple statement such as SELECT or INSERT, or it can be a compound statement written using BEGIN and END. Compound statement syntax is described in Section 20.2.7, “BEGIN … END Compound Statement”. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described later in this chapter. See, for example, Section 20.2.8, “DECLARE Statement”, and Section 20.2.12, “Flow Control Constructs”.

The CREATE FUNCTION statement was used in earlier versions of MySQL to support UDFs (User Defined Functions). See Section 27.3, “Adding New Functions to MySQL”. UDFs continue to be supported, even with the existence of stored functions. A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs.

A framework for external stored procedures will be introduced in the near future. This will allow you to write stored procedures in languages other than SQL. Most likely, one of the first languages to be supported is PHP because the core PHP engine is small, thread-safe, and can easily be embedded. Because the framework is public, it is expected that many other languages can also be supported.

A procedure or function is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither DETERMINISTIC nor NOT DETERMINISTIC is given, the default is NOT DETERMINISTIC.

For replication purposes, use of the NOW() function (or its synonyms) or RAND() does not necessarily make a routine non-deterministic. For NOW(), the binary log includes the timestamp and replicates correctly. RAND() also replicates correctly as long as it is invoked only once within a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Currently, the DETERMINISTIC characteristic is accepted, but not yet used by the optimizer. However, if binary logging is enabled, this characteristic affects whether MySQL accepts routine definitions. See Section 20.4, “Binary Logging of Stored Routines and Triggers”.

Several characteristics provide information about the nature of data use by the routine. CONTAINS SQL indicates that the routine does not contain statements that read or write data. NO SQL indicates that the routine contains no SQL statements. READS SQL DATA indicates that the routine contains statements that read data, but not statements that write data. MODIFIES SQL DATA indicates that the routine contains statements that may write data. CONTAINS SQL is the default if none of these characteristics is given explicitly.

The SQL SECURITY characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is DEFINER. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. In MySQL 5.1, it is necessary to have the EXECUTE privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the SQL SECURITY characteristic is set.

MySQL stores the sql_mode system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force.

The server uses the data type of a routine parameter or function return value as follows. These rules also apply to local routine variables created with the DECLARE statement (Section 20.2.9.1, "DECLARE Local Variables").

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict mode.
- For character data types, if there is a CHARACTER SET clause in the declaration, the specified character set and its default collation are used. If there is no such clause, the database character set and collation are used. (These are given by the values of the character_set_database and collation_database system variables.)
- Only scalar values can be assigned to parameters or variables. For example, a statement such as SET x = (SELECT 1, 2) is invalid.

The COMMENT clause is a MySQL extension, and may be used to describe the stored procedure. This information is displayed by the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements.

MySQL allows routines to contain DDL statements, such as CREATE and DROP. MySQL also allows stored procedures (but not stored functions) to contain SQL transaction statements such as COMMIT. Stored functions may not contain statements that do explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to allow them.

Stored routines cannot use LOAD DATA INFILE.

Statements that return a result set cannot be used within a stored function. This includes SELECT statements that do not use INTO to fetch column values into variables, SHOW statements, and other statements such as EXPLAIN. For statements that can be determined at function definition time to return a result set, a Not allowed to return a result set from a function error occurs (ER_SP_NO_RETSET_IN_FUNC). For statements that can be determined only at runtime to return a result set, a PROCEDURE %s can't return a result set in the given context error occurs (ER_SP_BADSELECT).

The following is an example of a simple stored procedure that uses an OUT parameter. The example uses the mysql client delimiter command to change the statement delimiter from ; to // while the procedure is being defined. This allows the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by mysql itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
    -> BEGIN
    ->   SELECT COUNT(*) INTO param1 FROM t;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+------+
| @a   |
+------+
| 3    |
+------+
1 row in set (0.00 sec)
```

When using the `delimiter` command, you should avoid the use of the backslash ('\') character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result:

```
mysql> delimiter //

mysql> CREATE FUNCTION hello (s CHAR(20)) RETURNS CHAR(50)
    -> RETURN CONCAT('Hello, ',s,'!');
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

If the `RETURN` statement in a stored function returns a value that has a different type than is specified in the function's `RETURNS` clause, the return value is coerced to the proper type. For example, if a function returns an `ENUM` or `SET` value, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

20.2.2. ALTER PROCEDURE and ALTER FUNCTION

```
ALTER {PROCEDURE | FUNCTION} sp_name [characteristic ...]

characteristic:
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

This statement can be used to change the characteristics of a stored procedure or function. In MySQL 5.1, you must have the `ALTER ROUTINE` privilege for the routine. This privilege is granted automatically to the routine creator. If binary logging is enabled, you may also need the `SUPER` privilege, as described in Section 20.4, "Binary Logging of Stored Routines and Triggers".

More than one change may be specified in an `ALTER PROCEDURE` or `ALTER FUNCTION` statement.

20.2.3. DROP PROCEDURE and DROP FUNCTION

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. In MySQL 5.1, you must have the `ALTER ROUTINE` privilege for the routine. This privilege is granted automatically to the routine creator.

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

20.2.4. SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION

```
SHOW CREATE {PROCEDURE | FUNCTION} sp_name
```

This statement is a MySQL extension. Similar to `SHOW CREATE TABLE`, it returns the exact string that can be used to re-create the named routine.

```
mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
       Function: hello
       sql_mode:
Create Function: CREATE FUNCTION `test`.`hello`(s CHAR(20)) RETURNS CHAR(50)
RETURN CONCAT('Hello, ',s,'!')
```

20.2.5. SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS

```
SHOW {PROCEDURE | FUNCTION} STATUS [LIKE 'pattern']
```

This statement is a MySQL extension. It returns characteristics of routines, such as the database, name, type, creator, and creation and modification dates. If no pattern is specified, the information for all stored procedures or all stored functions is listed, depending on which statement you use.

```
mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
*************************** 1. row ***************************
           Db: test
         Name: hello
         Type: FUNCTION
      Definer: testuser@localhost
     Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
Security_type: DEFINER
      Comment:
```

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See Section 23.1.14, “The `INFORMATION_SCHEMA ROUTINES` Table”.

20.2.6. CALL Statement

```
CALL sp_name([parameter[,...]])
```

The `CALL` statement invokes a procedure that was defined previously with `CREATE PROCEDURE`.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. It also “returns” the number of rows affected, which a client program can obtain at the SQL level by calling the `ROW_COUNT()` function and from C by calling the `mysql_affected_rows()` C API function.

20.2.7. BEGIN … END Compound Statement

```
[begin_label:] BEGIN
    [statement_list]
```

```
END [end_label]
```

Stored routines may contain multiple statements, using a `BEGIN ... END` compound statement. *`statement_list`* represents a list of one or more statements. Each statement within *`statement_list`* must be terminated by a semicolon character (`;`).

A compound statement can be labeled. *`end_label`* cannot be given unless *`begin_label`* also is present, and if both are present, they must be the same.

Please note that the optional `[NOT] ATOMIC` clause is not yet supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

Using multiple statements requires that a client is able to send query strings containing the `;` statement delimiter. This is handled in the `mysql` command-line client with the `delimiter` command. Changing the `;` end-of-query delimiter (for example, to `//`) allows `;` to be used in a routine body.

20.2.8. DECLARE Statement

The `DECLARE` statement is used to define various items local to a routine: local variables (see Section 20.2.9, "Variables in Stored Procedures"), conditions and handlers (see Section 20.2.10, "Conditions and Handlers") and cursors (see Section 20.2.11, "Cursors"). `SIGNAL` and `RESIGNAL` statements are not currently supported.

`DECLARE` may be used only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

20.2.9. Variables in Stored Procedures

You may declare and use variables within a routine.

20.2.9.1. DECLARE Local Variables

```
DECLARE var_name[,...] type [DEFAULT value]
```

This statement is used to declare local variables. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like routine parameters with respect to data type and overflow checking. See Section 20.2.1, "`CREATE PROCEDURE` and `CREATE FUNCTION`".

The scope of a local variable is within the `BEGIN ... END` block where it is declared. It can be used in nested blocks except those that declare a variable with the same name.

20.2.9.2. Variable SET Statement

```
SET var_name = expr [, var_name = expr] ...
```

The `SET` statement in stored procedures is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a routine, or global server variables.

The `SET` statement in stored procedures is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x, b=y, ...` where different variable types (locally declared variables and global and session server variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

20.2.9.3. SELECT ... INTO Statement

```
SELECT col_name[,...] INTO var_name[,...] table_expr
```

This SELECT syntax stores selected columns directly into variables. Therefore, only a single row may be retrieved.

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

Note that user variable names are *not* case sensitive in MySQL 5.1. See Section 9.3, "User Variables".

Important: SQL variable names should not be the same as column names. If an SQL statement, such as a SELECT ... INTO statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. For example, in the following statement, xname is interpreted as a reference to the xname *variable* rather than the xname *column*:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
  BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;

    SELECT xname,id INTO newname,xid
      FROM table1 WHERE xname = xname;
    SELECT newname;
  END;
```

When this procedure is called, the newname variable will return the value 'bob' regardless of the value of the table1.xname column.

See also Section I.1, "Restrictions on Stored Routines and Triggers".

20.2.10. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors, as well as general flow control inside a routine.

20.2.10.1. DECLARE Conditions

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
    SQLSTATE [VALUE] sqlstate_value
  | mysql_error_code
```

This statement specifies conditions that need specific handling. It associates a name with a specified error condition. The name can subsequently be used in a DECLARE HANDLER statement. See Section 20.2.10.2, "DECLARE Handlers".

In addition to SQLSTATE values, MySQL error codes are also supported.

20.2.10.2. DECLARE Handlers

```
DECLARE handler_type HANDLER FOR condition_value[,...] statement

handler_type:
    CONTINUE
  | EXIT
```

```
  | UNDO

condition_value:
    SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
  | mysql_error_code
```

The DECLARE ... HANDLER statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified *statement* is executed. *statement* can be a simple statement (for example, SET *var_name = value*), or it can be a compound statement written using BEGIN and END. Compound statement syntax is described in Section 20.2.7, "BEGIN ... END Compound Statement".

For a CONTINUE handler, execution of the current routine continues after execution of the handler statement. For an EXIT handler, execution terminates for the BEGIN...END compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The UNDO handler type statement is not yet supported.

- SQLWARNING is shorthand for all SQLSTATE codes that begin with 01.
- NOT FOUND is shorthand for all SQLSTATE codes that begin with 02.
- SQLEXCEPTION is shorthand for all SQLSTATE codes not caught by SQLWARNING or NOT FOUND.

In addition to SQLSTATE values, MySQL error codes are also supported.

For example:

```
mysql> CREATE TABLE test.t (s1 int,primary key (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
    -> BEGIN
    ->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    ->   SET @x = 1;
    ->   INSERT INTO test.t VALUES (1);
    ->   SET @x = 2;
    ->   INSERT INTO test.t VALUES (1);
    ->   SET @x = 3;
    -> END;
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
    +------+
    | @x   |
    +------+
    | 3    |
    +------+
    1 row in set (0.00 sec)
```

Notice that @x is 3, which shows that MySQL executed to the end of the procedure. If the line DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1; had not been present, MySQL would have taken the default (EXIT) path after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

If you want to ignore a condition, you can declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

20.2.11. Cursors

Simple cursors are supported inside stored procedures and functions. The syntax is as in embedded SQL. Cursors are currently asensitive, read-only, and non-scrolling. Asensitive means that the server may or may not make a copy of its result table.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

For example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT 0;
  DECLARE a CHAR(16);
  DECLARE b,c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '02000' SET done = 1;

  OPEN cur1;
  OPEN cur2;

  REPEAT
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF NOT done THEN
       IF b < c THEN
          INSERT INTO test.t3 VALUES (a,b);
       ELSE
          INSERT INTO test.t3 VALUES (a,c);
       END IF;
    END IF;
  UNTIL done END REPEAT;

  CLOSE cur1;
  CLOSE cur2;
END
```

20.2.11.1. Declaring Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be defined in a routine, but each cursor in a block must have a unique name.

The `SELECT` statement cannot have an `INTO` clause.

20.2.11.2. Cursor `OPEN` Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

20.2.11.3. Cursor `FETCH` Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

20.2.11.4. Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

20.2.12. Flow Control Constructs

The IF, CASE, LOOP, WHILE, ITERATE, and LEAVE constructs are fully implemented.

These constructs may each contain either a single statement, or a block of statements using the BEGIN ... END compound statement. Constructs may be nested.

FOR loops are not currently supported.

20.2.12.1. IF Statement

```
IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF
```

IF implements a basic conditional construct. If the *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search_condition* matches, the statement list in the ELSE clause is executed. *statement_list* can consist of one or more statements.

Please note that there is also an IF() *function*, which differs from the IF *statement* described here.. See Section 12.2, “Control Flow Functions”.

20.2.12.2. CASE Statement

```
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

The CASE statement for stored procedures implements a complex conditional construct. If a *search_condition* evaluates to true, the corresponding SQL statement is executed. If no search condition matches, the statement in the ELSE clause is executed.

Note: The syntax of a CASE *statement* shown here for use inside a stored procedure differs slightly from that of the SQL CASE *expression* described in Section 12.2, “Control Flow Functions”. The

CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

20.2.12.3. LOOP Statement

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of a particular statement or statements. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a LEAVE statement.

A LOOP statement can be labeled. *end_label* cannot be given unless *begin_label* also is present, and if both are present, they must be the same.

20.2.12.4. LEAVE Statement

```
LEAVE label
```

This statement is used to exit any labeled flow control construct. It can be used with BEGIN ... END or loops.

20.2.12.5. ITERATE Statement

```
ITERATE label
```

ITERATE can only appear within LOOP, REPEAT, and WHILE statements. ITERATE means "do the loop again."

For example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

20.2.12.6. REPEAT Statement

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement or statements within a REPEAT statement are repeated until the *search_condition* is true.

A REPEAT statement can be labeled. *end_label* cannot be given unless *begin_label* also is present, and if both are present, they must be the same.

For example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
```

```
    -> BEGIN
    ->   SET @x = 0;
    ->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+------+
| @x   |
+------+
| 1001 |
+------+
1 row in set (0.00 sec)
```

20.2.12.7. `WHILE` Statement

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement or statements within a `WHILE` statement are repeated as long as the *`search_condition`* is true.

A `WHILE` statement can be labeled. *`end_label`* cannot be given unless *`begin_label`* also is present, and if both are present, they must be the same.

For example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END
```

20.3. Stored Procedures, Functions, Triggers, and Replication: Frequently Asked Questions

- Do MySQL 5.1 stored procedures and functions work with replication?

  Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in Section 20.4, “Binary Logging of Stored Routines and Triggers”.

- Are stored procedures and functions created on a master server replicated to a slave?

  Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. `ALTER` and `DROP` statements for stored procedures and functions are also replicated.

- How are actions that take place inside stored procedures and functions replicated?

  MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

- Are there special security requirements for using stored procedures, functions and replication together?

  Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

  - Any user wishing to create stored functions must be granted the `SUPER` privilege.
  - Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which will allow anyone with the standard `CREATE ROUTINE` privilege to create stored functions.

- What limitations exist for replicating stored procedure and function actions?

  Non-deterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly cloned, and therefore, random actions replicated to a slave will not mirror those produced on a master. Note that declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 will not allow random-valued operations to be invoked.

  In addition, time-based actions cannot be reproduced on a slave as the timing of such actions in a stored procedure is not reproducible through the binary log used for replication as it only records DML events and does not factor in timing constraints.

  Finally, non-transactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

- Do the limitations described above affect MySQL's ability to do point-in-time recovery?

  The same limitations that affect replication do affect point-in-time recovery.

- What will MySQL do to correct the aforementioned limitations?

  A future release of MySQL is expected to feature a choice in how replication should be handled:

  - Statement-based replication (current implementation).
  - Row-level replication (that will solve all the limitations described earlier).

- Do triggers work with replication?

  Triggers and replication in MySQL 5.1 work the same as in most other database engines in that actions carried out through triggers on a master are not replicated to a slave server. Instead, triggers that exist on tables that reside on a MySQL master server need to be created on the tables that exist on any MySQL slave servers so that the triggers activate on the slaves as well as the master.

- How are actions carried out through triggers on a master replicated to a slave?

  First, the triggers that exist on a master must be recreated on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well.

The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it on the slave.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

20.4. Binary Logging of Stored Routines and Triggers

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of "events" that describe the modifications. The binary log has two important purposes:

- For replication, the master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 6.2, "Replication Implementation Overview".
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are reexecuted. These events bring databases up to date from the point of the backup. See Section 5.9.2.2, "Using Backups for Recovery".

This section describes how MySQL 5.1 handles binary logging for stored routines (procedures and functions) and triggers. It also states the current conditions that the implementation places on the use of stored routines, and then provides additional information about the reasons for these conditions.

In general, the issues described here result from the fact that binary logging occurs at the SQL statement level. A future MySQL release is expected to implement row-level binary logging, which specifies the changes to make to individual rows as a result of executing SQL statements.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See Section 5.11.3, "The Binary Log".) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  ```
  mysql> SET GLOBAL log_bin_trust_function_creators = 1;
  ```

You can also set this variable by using the `--log-bin-trust-function-creators` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is non-deterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the `SUPER` privilege and `log_bin_trust_function_creators` is 0.

The following discussion provides additional detail about the logging implementation and its implications.

- The server writes `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `DO` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents non-replication of data changes that result from use of stored functions in non-logged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `DO` *`func_name`*`()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

  ```
  CREATE FUNCTION f1(a INT) RETURNS INT
  BEGIN
    IF (a < 3) THEN
      INSERT INTO t2 VALUES (a);
    END IF;
  END;

  CREATE TABLE t1 (a INT);
  INSERT INTO t1 VALUES (1),(2),(3);

  SELECT f1(a) FROM t1;
  ```

  When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `DO` statement for each of them. That is, MySQL writes the following statements to the binary log:

  ```
  DO f1(1);
  DO f1(2);
  ```

  The server also logs a `DO` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `DO` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:

  - It is possible for a function to follow different execution paths on master and slave servers.

- Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the CREATE ROUTINE privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where the statement is processed by the SQL thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function unsafe_func() as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
    -> BEGIN
    ->   IF @@server_id=2 THEN dangerous_statement; END IF;
    ->   RETURN 1;
    -> END;
    -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The CREATE FUNCTION and INSERT statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statment. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the SUPER privilege, in addition to the usual CREATE ROUTINE privilege that is required. Similarly, to use ALTER FUNCTION, you must have the SUPER privilege in addition to the ALTER ROUTINE privilege. Without the SUPER privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the SUPER privilege (for example, if all users with the CREATE ROUTINE privilege on your system are experienced application developers), set the global log_bin_trust_function_creators system variable to 1. You can also set this variable by using the --log-bin-trust-function-creators option when starting the server. If binary logging is not enabled, log_bin_trust_function_creators does not apply and SUPER is not required for function creation.

- If a function that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:

  - It will make a slave different from the master.

  - Restored data will be different from the original data.

  To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

  - The DETERMINISTIC and NOT DETERMINISTIC characteristics indicate whether a function always produces the same result for given inputs. The default is NOT DETERMINISTIC if neither characteristic is given, so you must specify DETERMINISTIC explicitly to declare that a function is deterministic.

    Use of the NOW() function (or its synonyms) or RAND() does not necessarily make a function non-deterministic. For NOW(), the binary log includes the timestamp and replicates correctly. RAND() also replicates correctly as long as it is invoked only once within a function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, `DETERMINISTIC` or one of `NO SQL` and `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

Assessment of the nature of a function is based on the "honesty" of the creator: MySQL does not check that a function declared `DETERMINISTIC` contains no statements that produce nondeterministic results.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

  In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in non-procedure context:

  - A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

    `NAME_CONST(`*`var_name`*`, `*`var_value`*`)`

    `var_name` is the local variable name, and *`var_value`* is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of *`var_value`*, and a "name" of *`var_name`*. Thus, if you invoke this function directly, you get a result like this:

    ```
    mysql> SELECT NAME_CONST('myname', 14);
    +--------+
    | myname |
    +--------+
    |     14 |
    +--------+
    ```

    `NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

  - A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where *`value`* is the value of `@my_var` on the master:

```
SET @my_var = value;
```

  - Procedure calls can occur within a committed or rolled-back transaction. Previously, `CALL` statements were logged even if they occurred within a rolled-back transaction. As of MySQL 5.0.12, transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

    - Updates to transactional tables are not logged.

    - Updates to non-transactional tables are logged because rollback does not cancel them.

    - Updates to a mix of transactional and non-transactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 21. Triggers

A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table. For example, the following statements create a table and an INSERT trigger. The trigger sums the values inserted into one of the table's columns:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    -> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

This chapter describes the syntax for creating and dropping triggers, and shows some examples of how to use them. Discussion of restrictions on use of triggers is given in Appendix I, *Feature Restrictions*. Remarks regarding binary logging as it applies to triggers are given in Section 20.4, “Binary Logging of Stored Routines and Triggers”.

21.1. CREATE TRIGGER Syntax

```
CREATE
    [DEFINER = { user | CURRENT_USER }]
    TRIGGER trigger_name trigger_time trigger_event
    ON tbl_name FOR EACH ROW trigger_stmt
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. CREATE TRIGGER requires the SUPER privilege.

The trigger becomes associated with the table named *tbl_name*, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

The DEFINER clause determines the privileges that apply when the trigger is activated.

trigger_time is the trigger action time. It can be BEFORE or AFTER to indicate that the trigger activates before or after the statement that activated it.

trigger_event indicates the kind of statement that activates the trigger. The *trigger_event* can be one of the following:

- INSERT: The trigger is activated whenever a new row is inserted into the table; for example, through INSERT, LOAD DATA, and REPLACE statements.
- UPDATE: The trigger is activated whenever a row is modified; for example, through UPDATE statements.
- DELETE: The trigger is activated whenever a row is deleted from the table; for example, through DELETE and REPLACE statements.

It is important to understand that the *trigger_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an INSERT trigger is activated by not only INSERT statements but also LOAD DATA statements because both statements insert rows into a table.

A potentially confusing example of this is the INSERT INTO .. ON DUPLICATE UPDATE ... syntax: a BEFORE INSERT trigger will activate for every row, followed by either an AFTER INSERT trigger or both the BEFORE UPDATE and AFTER UPDATE triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_stmt` is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See Section 20.2.7, "`BEGIN ... END` Compound Statement".

Note: Currently, triggers are not activated by cascaded foreign key actions. This limitation will be lifted as soon as possible.

In MySQL 5.1, you can write triggers containing direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

DELIMITER |

CREATE TRIGGER testref BEFORE INSERT ON test1
  FOR EACH ROW BEGIN
    INSERT INTO test2 SET a2 = NEW.a1;
    DELETE FROM test3 WHERE a3 = NEW.a1;
    UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
  END
|

DELIMITER ;

INSERT INTO test3 (a3) VALUES
  (NULL), (NULL), (NULL), (NULL), (NULL),
  (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
  (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
    -> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
+------+
| a1   |
+------+
|    1 |
|    3 |
|    1 |
|    7 |
|    1 |

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

The `DEFINER` clause specifies the account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format as for the `GRANT` statement). The `user_name` and `host_name` values both are required. `CURRENT_USER` also can be given as `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, you cannot set the value to any account but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the

account does not actually exist, a warning is generated.

MySQL checks trigger privileges like this:

- At `CREATE TRIGGER` time, the user that issues the statement must have the `SUPER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `SUPER` privilege.
  - The `SELECT` privilege for the subject table if references to table columns occur via `OLD.col_name` or `NEW.col_name` in the trigger definition.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger definition.
  - Whatever other privileges normally are required for the statements executed by the trigger.

21.2. DROP TRIGGER Syntax

```
DROP TRIGGER [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` was added in MySQL 5.0.2. Its use requires the `SUPER` privilege.

Note: When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or newer — including all MySQL 5.1 releases — you must drop all triggers *before upgrading* and re-create them afterwards, or else `DROP TRIGGER` does not work after the upgrade. See Section 2.10.1, “Upgrading from MySQL 5.0”, for a suggested upgrade procedure.

21.3. Using Triggers

This section discusses how to use triggers in MySQL 5.1 and what limitations exist regarding their use.

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is associated with a table and is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement for the table executes. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is deleted from a table or after each row that is updated.

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in Section 21.1, “`CREATE TRIGGER` Syntax”, and Section 21.2, “`DROP TRIGGER` Syntax”.

Here is a simple example that associates a trigger with a table for `INSERT` statements. It acts as an accumulator to sum the values inserted into one of the columns of the table.

The following statements create a table and a trigger for it:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    -> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

The CREATE TRIGGER statement creates a trigger named ins_sum that is associated with the account table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword BEFORE indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is AFTER.
- The keyword INSERT indicates the event that activates the trigger. In the example, INSERT statements cause trigger activation. You can also create triggers for DELETE and UPDATE statements.
- The statement following FOR EACH ROW defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement In the example, the triggered statement is a simple SET that accumulates the values inserted into the amount column. The statement refers to the column as NEW.amount which means "the value of the amount column to be inserted into the new row."

To use the trigger, set the accumulator variable to zero, execute an INSERT statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+----------------------+
| Total amount inserted |
+----------------------+
| 1852.48              |
+----------------------+
```

In this case, the value of @sum after the INSERT statement has executed is 14.98 + 1937.50 - 100 or 1852.48.

To destroy the trigger, use a DROP TRIGGER statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two BEFORE INSERT triggers or two AFTER UPDATE triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the BEGIN ... END compound statement construct after FOR EACH ROW. (An example appears later in this section.)

The OLD and NEW keywords enable you to access columns in the rows affected by a trigger. (OLD and NEW are not case sensitive.) In an INSERT trigger, only NEW.*col_name* can be used; there is no old row. In a DELETE trigger, only OLD.*col_name* can be used; there is no new row. In an UPDATE trigger, you can use OLD.*col_name* to refer to the columns of a row before it is updated and NEW.*col_name* to refer to the columns of the row after it is updated.

A column named with OLD is read-only. You can refer to it but not modify it. A column named with NEW can be referred to if you have the SELECT privilege for it. In a BEFORE trigger, you can also change its value with SET NEW.*col_name* = *value* if you have the UPDATE privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a BEFORE trigger, the NEW value for an AUTO_INCREMENT column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

OLD and NEW are MySQL extensions to triggers.

By using the BEGIN ... END construct, you can define a trigger that executes multiple statements. Within the BEGIN block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the mysql program to define a trigger that executes multiple statements, it is necessary to redefine the mysql statement delimiter so that you can use the ';' character within the trigger definition. The following example illustrates these points. It defines an UPDATE trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a BEFORE trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    -> FOR EACH ROW
    -> BEGIN
    ->     IF NEW.amount < 0 THEN
    ->         SET NEW.amount = 0;
    ->     ELSEIF NEW.amount > 100 THEN
    ->         SET NEW.amount = 100;
    ->     END IF;
    -> END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple CALL statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the CALL statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through OUT or INOUT parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as START TRANSACTION, COMMIT, or ROLLBACK.

MySQL handles errors during trigger execution as follows:

- If a BEFORE trigger fails, the operation on the corresponding row is not performed.
- An AFTER trigger is executed only if the BEFORE trigger (if any) and the row operation both execute successfully.
- An error during either a BEFORE or AFTER trigger results in failure of the whole statement that caused trigger invocation.
- For transactional tables, failure of a trigger (and thus the whole statement) should cause rollback of all changes performed by the statement. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Chapter 22. Views

Views (including updatable views) are available in the 5.1 version of MySQL Server.

This chapter discusses the following topics:

- Creating or altering views with `CREATE VIEW` or `ALTER VIEW`
- Destroying views with `DROP VIEW`
- Displaying view metadata with `SHOW CREATE VIEW`

Discussion of restrictions on use of views is given in Appendix I, *Feature Restrictions*.

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See Section 2.10.2, "Upgrading the Grant Tables".

22.1. `ALTER VIEW` Syntax

```
ALTER
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = { user | CURRENT_USER }]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of an existing view. The syntax is similar to that for `CREATE VIEW`. See Section 22.2, "`CREATE VIEW` Syntax". This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement.

22.2. `CREATE VIEW` Syntax

```
CREATE
    [OR REPLACE]
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = { user | CURRENT_USER }]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. The *`select_statement`* is a `SELECT` statement that provides the definition of the view. The statement can select from base tables or other views.

This statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as *`db_name.view_name`* when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Tables and views share the same namespace within a database, so a database cannot contain a table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the SELECT statement are used for the view column names. To define explicit names for the view columns, the optional *column_list* clause can be given as a list of comma-separated identifiers. The number of names in *column_list* must be the same as the number of columns retrieved by the SELECT statement.

Columns retrieved by the SELECT statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the SELECT statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    3 |    50 |   150 |
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The SELECT statement cannot contain a subquery in the FROM clause.
- The SELECT statement cannot refer to system or user variables.
- The SELECT statement cannot refer to prepared statement parameters.
- Within a stored routine, the definition cannot refer to routine parameters or local variables.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. To check a view definition for problems of this kind, use the CHECK TABLE statement.
- The definition cannot refer to a TEMPORARY table, and you cannot create a TEMPORARY view.
- The tables named in the view definition must already exist.
- You cannot associate a trigger with a view.

ORDER BY is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own ORDER BY.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a LIMIT clause, and you select from the view using a statement that has its own LIMIT clause, it is undefined which limit applies. This same principle applies to options such as ALL, DISTINCT, or SQL_SMALL_RESULT that follow the SELECT keyword, and to clauses such as INTO, FOR UPDATE, LOCK IN SHARE MODE, and PROCEDURE.

If you create a view and then change the query processing environment by changing system variables, that may affect the results you get from the view:

```
mysql> CREATE VIEW v AS SELECT CHARSET(CHAR(65)), COLLATION(CHAR(65));
Query OK, 0 rows affected (0.00 sec)

mysql> SET NAMES 'latin1';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM v;
+-------------------+----------------------+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-------------------+----------------------+
| latin1            | latin1_swedish_ci    |
+-------------------+----------------------+
1 row in set (0.00 sec)

mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM v;
+-------------------+----------------------+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-------------------+----------------------+
| utf8              | utf8_general_ci      |
+-------------------+----------------------+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. They were addded in MySQL 5.1.2.

`CURRENT_USER` also can be given as `CURRENT_USER()`.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine creator. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. (This is the same as `DEFINER = CURRENT_USER`.) If a *`user`* value is given, it should be a MySQL account in '*`user_name`*'@'*`host_name`*' format (the same format as for the `GRANT` statement). The *`user_name`* and *`host_name`* values both are required.

If you specify the `DEFINER` clause, you cannot set the value to any user but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal *`user`* value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

The `SQL SECURITY` characteristic determines which account to use when checking access privileges for the view when the view is executed. The legal characteristic values are `DEFINER` and `INVOKER`. These indicate that the view must be executable by the user who defined it or invoked it, respectively. The default `SQL SECURITY` value is `DEFINER`.

As of MySQL 5.1.2, view privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the

function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.

- At view execution time, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If view execution causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a `SQL SECURITY` characteristic of `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, privileges within the function runs with the privileges of its creator. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Prior to MySQL 5.1.2 (before the `DEFINE` and `SQL SECURITY` clauses were implemented), privileges required for objects used in a view are checked at view creation time.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges need to be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the function `f()` and the view `v`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

If you invoke a view that was created before MySQL 5.0.13/5.1.2, it is treated as though it was created with a `SQL SECURITY INVOKER` clause and with a `DEFINER` value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to recreate the view so that the view definition includes a `DEFINER` clause.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. The algorithm affects how MySQL processes the view.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be UNDEFINED three ways:

- No ALGORITHM clause is present in the CREATE VIEW statement.
- The CREATE VIEW statement has an explicit ALGORITHM = UNDEFINED clause.
- ALGORITHM = MERGE is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to UNDEFINED.

As mentioned earlier, MERGE is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the MERGE algorithm works. The examples assume that there is a view v_merge that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- v_merge becomes t
- * becomes vc1, vc2, which corresponds to c1, c2
- The view WHERE clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that vc1 < 100 becomes c1 < 100 and the view WHERE clause is added to the statement WHERE clause using an AND connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a WHERE clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

The MERGE algorithm requires a one-to relationship between the rows in the view and the rows in the underlying table. If this relationship does not hold, a temporary table must be used instead. Lack of a one-to-one relationship occurs if the view contains any of a number of constructs:

- Aggregate functions (SUM(), MIN(), MAX(), COUNT(), and so forth)
- DISTINCT

- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Refers only to literal values (in this case, there is no underlying table)

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Join
- Non-updatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view non-updatable)

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

  ```
  3.14159
  col1 + 3
  UPPER(col2)
  col3 / col4
  (subquery)
  ```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the *`select_statement`* is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
    -> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
    -> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
    -> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
ql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.3.3, “Server System Variables”.

`INFORMATION_SCHEMA` contains a `VIEWS` table from which information about view objects can be obtained. See Section 23.1.15, “The `INFORMATION_SCHEMA VIEWS` Table”.

22.3. `DROP VIEW` Syntax

```
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

You can use the keywords `IF EXISTS` to prevent an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See Section 13.5.4.22, "`SHOW WARNINGS` Syntax".

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

22.4. `SHOW CREATE VIEW` Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows a `CREATE VIEW` statement that creates the given view.

```
mysql> SHOW CREATE VIEW v;
+------+----------------------------------------------------+
| View | Create View                                        |
+------+----------------------------------------------------+
| v    | CREATE VIEW `test`.`v` AS select 1 AS `a`,2 AS `b` |
+------+----------------------------------------------------+
```

Chapter 23. The INFORMATION_SCHEMA Database

INFORMATION_SCHEMA provides access to database metadata.

Metadata is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

Here is an example:

```
mysql> SELECT table_name, table_type, engine
    -> FROM information_schema.tables
    -> WHERE table_schema = 'db5'
    -> ORDER BY table_name DESC;
+------------+------------+--------+
| table_name | table_type | engine |
+------------+------------+--------+
| v56        | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v          | VIEW       | NULL   |
| tables     | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t          | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| loop       | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| goto       | BASE TABLE | MyISAM |
| fk2        | BASE TABLE | InnoDB |
| fk         | BASE TABLE | InnoDB |
+------------+------------+--------+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database db5, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its engine.

INFORMATION_SCHEMA is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside INFORMATION_SCHEMA there are several read-only tables. They are actually views, not base tables, so you won't actually see any file associated with them.

Each MySQL user has the right to access these tables, but only the rows in the tables that correspond to objects for which the user has the proper access privileges.

Advantages of SELECT

The SELECT ... FROM INFORMATION_SCHEMA statement is intended as a more consistent way to provide access to the information provided by the various SHOW statements that MySQL supports (SHOW DATABASES, SHOW TABLES, and so forth). Using SELECT has these advantages, compared to SHOW:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how SELECT works, they only need to learn the object names.

- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because SHOW is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate SHOW. In fact, there are enhancements to SHOW in MySQL 5.1 as well. These are described in Section 23.2, "Extensions to SHOW Statements".

Standards

The implementation for the INFORMATION_SCHEMA table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the engine column in the INFORMATION_SCHEMA.TABLES table.

Although other DBMSs use a variety of names, like syscat or system, the standard name is INFORMATION_SCHEMA.

In effect, we have a new database named INFORMATION_SCHEMA, though there is never a need to make a file by that name. It is possible to select INFORMATION_SCHEMA as the default database with a USE statement, but the only way to access the contents of its tables is with SELECT. You cannot insert into them, update them, or delete from them.

Privileges

There is no difference between the current (SHOW) privilege requirement and the SELECT requirement. In either case, you have to have some privilege on an object in order to see information about it.

23.1. INFORMATION_SCHEMA Tables

Explanation of following sections

In the following sections, we take the tables and columns that are in INFORMATION_SCHEMA. For each column, there are three pieces of information:

- "Standard Name" indicates the standard SQL name for the column.
- "SHOW name" indicates what the equivalent field name is in the closest SHOW statement, if any.
- "Remarks" provides additional information where applicable.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of columns marked **MySQL extension**. (For example, we changed COLLATION to TABLE_COLLATION in the TABLES table.) See the list of reserved words near the end of this article: http://www.dbazine.com/gulutzan5.shtml.

The definition for character columns (for example, TABLES.TABLE_NAME), is generally VARCHAR(*N*) CHARACTER SET utf8 where *N* is at least 64.

Each section indicates what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA, or else that there is no such equivalent statement.

Note: At present, there are some missing columns and some columns out of order. We are working on this and intend to update the documentation as changes are made.

23.1.1. The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the SCHEMATA table provides information about databases.

Standard Name	SHOW name	Remarks
CATALOG_NAME	-	NULL
SCHEMA_NAME		Database
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		
SQL_PATH		NULL

Note: The value of the SQL_PATH column is always NULL.

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database
    FROM INFORMATION_SCHEMA.SCHEMATA
    [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
    [LIKE 'wild']
```

23.1.2. The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension

TABLE_COMMENT	Comment	MySQL extension

Notes:

- TABLE_SCHEMA and TABLE_NAME are a single field in a SHOW display, for example Table_in_db1.
- TABLE_TYPE should be BASE TABLE or VIEW. If table is temporary, then TABLE_TYPE = TEMPORARY. (There are no temporary views, so this is not ambiguous.)
- The TABLE_ROWS column is NULL if the table is in the INFORMATION_SCHEMA database. For InnoDB tables, the row count is only a rough estimate used in SQL optimization.
- We have nothing for the table's default character set. TABLE_COLLATION is close, because collation names begin with a character set name.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  [WHERE table_schema = 'db_name']
  [WHERE|AND table_name LIKE 'wild']

SHOW TABLES
  [FROM db_name]
  [LIKE 'wild']
```

23.1.3. The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In SHOW, the Type display includes values from several different COLUMNS columns.
- ORDINAL_POSITION is necessary because you might someday want to say ORDER BY ORDINAL_POSITION. Unlike SHOW, SELECT does not have automatic ordering.
- CHARACTER_OCTET_LENGTH should be the same as CHARACTER_MAXIMUM_LENGTH, except for multi-byte character sets.
- CHARACTER_SET_NAME can be derived from Collation. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the Collation column a value of latin1_swedish_ci, the character set is what's before the first underscore: latin1.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
  FROM INFORMATION_SCHEMA.COLUMNS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']
  [AND column_name LIKE 'wild']

SHOW COLUMNS
  FROM tbl_name
  [FROM db_name]
  [LIKE wild]
```

23.1.4. The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for sp_statistics, except that we replaced the name QUALIFIER with CATALOG

and we replaced the name OWNER with SCHEMA.

Clearly, the preceding table and the output from SHOW INDEX are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']

SHOW INDEX
  FROM tbl_name
  [FROM db_name]
```

23.1.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The USER_PRIVILEGES table provides information about global privileges. This information comes from the mysql.user grant table.

Standard Name	SHOW name	Remarks
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- This is a non-standard table. It takes its values from the mysql.user table.

23.1.6. The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The SCHEMA_PRIVILEGES table provides information about schema (database) privileges. This information comes from the mysql.db grant table.

Standard Name	SHOW name	Remarks
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
TABLE_SCHEMA		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- This is a non-standard table. It takes its values from the mysql.db table.

23.1.7. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The TABLE_PRIVILEGES table provides information about table privileges. This information comes from the mysql.tables_priv grant table.

Standard Name	SHOW name	Remarks
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
```

```
SHOW GRANTS ...
```

PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP, CREATE VIEW.

23.1.8. The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. This information comes from the mysql.columns_priv grant table.

Standard Name	SHOW name	Remarks
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from SHOW FULL COLUMNS, the privileges are all in one field and in lowercase, for example, select,insert,update,references. In COLUMN_PRIVILEGES, there is one row per privilege, and it's uppercase.
- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES.
- If the user has GRANT OPTION privilege, IS_GRANTABLE should be YES. Otherwise, IS_GRANTABLE should be NO. The output does not list GRANT OPTION as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...
```

23.1.9. The INFORMATION_SCHEMA CHARACTER_SETS Table

The CHARACTER_SETS table provides information about available character sets.

Standard Name	SHOW name	Remarks
CHARACTER_SET_NAME	Charset	
DEFAULT_COLLATE_NAME	Default collation	
DESCRIPION	Description	MySQL extension
MAXLEN	Maxlen	MySQL extension

Notes:

- We have added two non-standard columns corresponding to the Description and Maxlen columns in the output from SHOW CHARACTER SET.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE name LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

23.1.10. The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set.

Standard Name	SHOW name	Remarks
COLLATION_NAME	Collation	

Notes:

- We have added five non-standard columns corresponding to the Charset, Id, Default, Compiled, and Sortlen columns in the output from SHOW COLLATION.

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE collation_name LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

23.1.11. The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The COLLATION_CHARACTER_SET_APPLICABILITY table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from SHOW COLLATION.

Standard Name	SHOW name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

23.1.12. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

Standard Name	SHOW name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

Notes:

- The CONSTRAINT_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.
- The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key_name field in the output from SHOW INDEX when the Non_unique field is 0.
- The CONSTRAINT_TYPE column can contain one of these values: UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK. This is a CHAR (not ENUM) column. The CHECK value is not available until we support CHECK.

23.1.13. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

Standard Name	SHOW name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		

POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of ORDINAL_POSITION is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of POSITION_IN_UNIQUE_CONSTRAINT is NULL for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

  For example, suppose that there are two tables name t1 and t3 that have the following definitions:

```
CREATE TABLE t1
(
    s1 INT,
    s2 INT,
    s3 INT,
    PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
    s1 INT,
    s2 INT,
    s3 INT,
    KEY(s1),
    CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

  For those two tables, the KEY_COLUMN_USAGE table has two rows:

  - One row with CONSTRAINT_NAME='PRIMARY', TABLE_NAME='t1', COLUMN_NAME='s3', ORDINAL_POSITION=1, POSITION_IN_UNIQUE_CONSTRAINT=NULL.
  - One row with CONSTRAINT_NAME='CO', TABLE_NAME='t3', COLUMN_NAME='s2', ORDINAL_POSITION=1, POSITION_IN_UNIQUE_CONSTRAINT=1.

23.1.14. The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs) at this time.

The column named "mysql.proc name" indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

Standard Name	mysql.proc name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL

ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE|FUNCTION}
DTD_IDENTIFIER		(data type descriptor)
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension

Notes:

- MySQL calculates EXTERNAL_LANGUAGE thus:
  - If mysql.proc.language='SQL', then EXTERNAL_LANGUAGE is NULL
  - Otherwise, EXTERNAL_LANGUAGE is what's in mysql.proc.language. However, we don't have external languages yet, so it's always NULL.

23.1.15. The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		

Notes:

- There is a new privilege, SHOW VIEW, without which you cannot see the VIEWS table.

- The VIEW_DEFINITION column has most of what you see in the Create Table field that SHOW CREATE VIEW produces. Skip the words before SELECT and skip the words WITH CHECK OPTION. For example, if the original statement was:

  ```
  CREATE VIEW v AS
    SELECT s2,s1 FROM t
    WHERE s1 > 5
    ORDER BY s1
    WITH CHECK OPTION;
  ```

  then the view definition is:

  ```
  SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
  ```

- The CHECK_OPTION column always has a value of NONE.
- The IS_UPDATABLE column is YES if the view is updatable, NO if the view is not updatable.
- The DEFINER column indicates who defined the view. SECURITY_TYPE has a value of DEFINER or INVOKER.

23.1.16. The INFORMATION_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers.

You must have the SUPER privilege to view this table.

Standard Name	SHOW name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		
DEFINER		

Notes:

- The TRIGGER_SCHEMA and TRIGGER_NAME columns contain the name of the database in

which the trigger occurs, and the trigger name, respectively.

- The EVENT_MANIPULATION column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.

- As noted in Chapter 21, *Triggers*, every trigger is associated with exactly one table. The EVENT_OBJECT_SCHEMA and EVENT_OBJECT_TABLE columns contain the database in which this table occurs, and the table's name.

- The ACTION_ORDER statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same EVENT_MANIPULATION and ACTION_TIMING on the same table.

- The ACTION_STATEMENT column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the Statement column of the output from SHOW TRIGGERS. Note that this text uses UTF-8 encoding.

- The ACTION_ORIENTATION column always contains the value 'ROW'.

- The ACTION_TIMING column contains one of the two values 'BEFORE' or 'AFTER'.

- The columns ACTION_REFERENCE_OLD_ROW and ACTION_REFERENCE_NEW_ROW contain the old and new column identifiers, respectively. This means that ACTION_REFERENCE_OLD_ROW always contains the value 'OLD' and ACTION_REFERENCE_NEW_ROW always contains the value 'NEW'.

- The SQL_MODE column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the sql_mode system variable. See Section 5.3.2, “The Server SQL Mode”.

- The DEFINER column was added in MySQL 5.1.2. DEFINER indicates who defined the trigger.

- The following columns currently always contain NULL: TRIGGER_CATALOG, EVENT_OBJECT_CATALOG, ACTION_CONDITION, ACTION_REFERENCE_OLD_TABLE, ACTION_REFERENCE_NEW_TABLE, and CREATED.

Example, using the ins_sum trigger defined in Section 21.3, “Using Triggers”:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
*************************** 1. row ***************************
           TRIGGER_CATALOG: NULL
            TRIGGER_SCHEMA: test
              TRIGGER_NAME: ins_sum
        EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: NULL
       EVENT_OBJECT_SCHEMA: test
        EVENT_OBJECT_TABLE: account
              ACTION_ORDER: 0
          ACTION_CONDITION: NULL
          ACTION_STATEMENT:  SET @sum = @sum + NEW.amount
        ACTION_ORIENTATION: ROW
             ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
ACTION_REFERENCE_NEW_TABLE: NULL
  ACTION_REFERENCE_OLD_ROW: OLD
  ACTION_REFERENCE_NEW_ROW: NEW
                  CREATED: NULL
1 row in set (1.54 sec)
```

See also Section 13.5.4.20, “SHOW TRIGGERS Syntax”.

23.1.17. Other INFORMATION_SCHEMA Tables

We intend to implement additional INFORMATION_SCHEMA tables. In particular, we acknowledge the need for INFORMATION_SCHEMA.PARAMETERS and for INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS.

23.2. Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION_SCHEMA:

- SHOW can be used to get information about the structure of INFORMATION_SCHEMA itself.
- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

INFORMATION_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION_SCHEMA to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+---------------------------------------+
| Tables_in_information_schema          |
+---------------------------------------+
| SCHEMATA                              |
| TABLES                                |
| COLUMNS                               |
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| ROUTINES                              |
| STATISTICS                            |
| VIEWS                                 |
| TRIGGERS                              |
| USER_PRIVILEGES                       |
| SCHEMA_PRIVILEGES                     |
| TABLE_PRIVILEGES                      |
| COLUMN_PRIVILEGES                     |
| TABLE_CONSTRAINTS                     |
| KEY_COLUMN_USAGE                      |
+---------------------------------------+
```

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

Several SHOW statement have been extended to allow a WHERE clause:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW KEYS
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW VARIABLES
```

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW CHARACTER SET statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |      1 |

...
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `"japanese"`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| big5    | Big5 Traditional Chinese  | big5_chinese_ci     |      2 |

Chapter 24. Precision Math

MySQL 5.1 provides support for precision math, that is, numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data. (See Section 5.3.2, “The Server SQL Mode”.)
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, a number such as `.0001` is treated as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that merely “close” to 1.
- **Well-defined rounding behavior**: For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable. (See Section 5.3.2, “The Server SQL Mode”.)

An important result of these features is that MySQL 5.1 provides a high degree of compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5.1 handles numeric operations precisely.

24.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Numbers that look similar need not be both exact-value or both approximate-value. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

24.2. DECIMAL Data Type Changes

This section discusses the characteristics of the DECIMAL data type (and its synonyms) in MySQL 5.1, particularly with regard to the following:

- Maximum number of digits
- Storage format
- Storage requirements
- The non-standard MySQL extension to the upper range of DECIMAL columns

Possible incompatibilities with applications that are written for older versions of MySQL are noted throughout this section.

The declaration syntax for a DECIMAL column is DECIMAL(*M*,*D*). The ranges of values for the arguments in MySQL 5.1 are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL allowed a range of 1 to 254.)
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for DECIMAL columns in MySQL 5.1 are stored using a binary format that packs nine decimal digits into four bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and any digits left over require some fraction of four bytes. For example, a DECIMAL(18,9) column has nine digits on either side of the decimal point, so the integer part and the fractional part each require four bytes. A DECIMAL(20,10) column has ten digits on either side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for leftover digits is given by the following table:

Digits Left Over	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4

9	4

Unlike some older versions of MySQL, `DECIMAL` columns in MySQL 5.1 do not store a leading `+` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns in MySQL 5.1 do not allow values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(`*`M`*`,`*`D`*`)` column allows at most *`M`* – *`D`* digits to the left of the decimal point. (This is not compatible with applications relying on older versions of MySQL that allowed storing an extra digit in lieu of a `+` sign.)

The SQL standard requires that the precision of `NUMERIC(`*`M`*`,`*`D`*`)` be *exactly* *`M`* digits. For `DECIMAL(`*`M`*`,`*`D`*`)`, the standard requires a precision of at least *`M`* digits but allows more. In MySQL, `DECIMAL(`*`M`*`,`*`D`*`)` and `NUMERIC(`*`M`*`,`*`D`*`)` are the same, and both have a precision of exactly *`M`* digits.

For more detailed information about porting applications that relied on the old treatment of the `DECIMAL` data type, see the *MySQL 5.0 Reference Manual*.

24.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for `INSERT` is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. (The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.)
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the sql_mode system variable. (See Section 1.9.2, “Selecting SQL Modes”.) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET SQL_MODE='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it should be inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in *Rounding Behavior*.

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handing is undefined.

By default, division by zero produces a result of `NULL` and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

`sql_mode` Value	**Result**
`''` (Default)	No warning, no error; `i` is set to `NULL`.
strict	No warning, no error; `i` is set to `NULL`.
`ERROR_FOR_DIVISION_BY_ZERO`	Warning, no error; `i` is set to `NULL`.
strict,`ERROR_FOR_DIVISION_BY_ZERO`	Error condition; no row inserted.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. *This includes the empty string*.
- A string that begins with a number can be converted, but the trailing non-numeric portion is truncated. This produces an error in strict mode, or a warning otherwise.

24.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into `DECIMAL` columns.

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negat-

ive. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
+------------+--------------+
```

For inserts into a `DECIMAL` column, the target is an exact data type, so rounding uses "round half up," regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SELECT d FROM t;
+------+
| d    |
+------+
| 3    |
| 3    |
+------+
```

24.5. Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.1.

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT .1 + .2 = .3;
+--------------+
| .1 + .2 = .3 |
+--------------+
|            1 |
+--------------+
```

However, for floating-point values, results are inexact:

```
mysql> SELECT .1E0 + .2E0 = .3E0;
+--------------------+
| .1E0 + .2E0 = .3E0 |
+--------------------+
|                  0 |
+--------------------+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
```

```
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+--------+------------------+
| d      | f                |
+--------+------------------+
| 1.0000 | 0.99999999999991 |
+--------+------------------+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers *X1* and *X2* that have scale *S1* and *S2*, the scale of the result is *S1 + S2*:

```
mysql> SELECT .01 * .01;
+-----------+
| .01 * .01 |
+-----------+
| 0.0001    |
+-----------+
```

Example 3. Rounding behavior is well-defined:

In MySQL 5.1, rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

In MySQL 5.1, rounding for `DECIMAL` columns and exact-valued numbers uses the “round half up” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+------------+-------------+
| ROUND(2.5) | ROUND(-2.5) |
+------------+-------------+
| 3          | -3          |
+------------+-------------+
```

However, rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+--------------+---------------+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+--------------+---------------+
|            2 |            -2 |
+--------------+---------------+
```

Example 4. In strict mode, inserting a value that is too large results in overflow and causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET SQL_MODE='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
|  127 |
+------+
1 row in set (0.00 sec)
```

Howver, an overflow condition occurs if strict mode is in effect:

```
mysql> SET SQL_MODE='TRADITIONAL';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.10 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, and not a result of `NULL`.

In non-strict mode, division by zero has a result of `NULL`:

```
mysql> SET SQL_MODE='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.06 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
| NULL |
+------+
1 row in set (0.01 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET SQL_MODE='TRADITIONAL';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. In MySQL 4 (before precision math was introduced), both exact-value and approximate-value literals were converted to double-precision floating-point values:

```
mysql> SELECT VERSION();
+-----------------+
| VERSION()       |
+-----------------+
| 4.0.25-standard |
+-----------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;

mysql> DESCRIBE t;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| a     | double(3,1) |      |     | 0.0     |       |
| b     | double      |      |     | 0       |       |
+-------+-------------+------+-----+---------+-------+
```

In MySQL 5.1, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as `DECIMAL`:

```
mysql> SELECT VERSION();
+-----------------+
| VERSION()       |
+-----------------+
| 5.1.2-alpha-log |
+-----------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;

mysql> DESCRIBE t;
+-------+--------------+------+-----+---------+-------+
| Field | Type         | Null | Key | Default | Extra |
+-------+--------------+------+-----+---------+-------+
| a     | decimal(2,1) | NO   |     | 0.0     |       |
| b     | double       | NO   |     | 0       |       |
+-------+--------------+------+-----+---------+-------+
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result in MySQL 4.0 or 4.1 (prior to the introduction of precision math in MySQL):

```
mysql> DESCRIBE y;
```

```
+--------+--------------+------+-----+---------+-------+
| Field  | Type         | Null | Key | Default | Extra |
+--------+--------------+------+-----+---------+-------+
| AVG(i) | double(17,4) | YES  |     | NULL    |       |
| AVG(d) | double(17,4) | YES  |     | NULL    |       |
| AVG(f) | double       | YES  |     | NULL    |       |
+--------+--------------+------+-----+---------+-------+
```

The result is a double no matter the argument type.

Result in MySQL 5.1:

```
mysql> DESCRIBE y;
+--------+---------------+------+-----+---------+-------+
| Field  | Type          | Null | Key | Default | Extra |
+--------+---------------+------+-----+---------+-------+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+--------+---------------+------+-----+---------+-------+
```

The result is a double only for the floating-point argument. *For exact type arguments, the result is also an exact type.*

Chapter 25. APIs and Libraries

This chapter describes the APIs available for MySQL, where to get them, and how to use them. The C API is the most extensively covered, because it was developed by the MySQL team, and is the basis for most of the other APIs. This chapter also covers the `libmysqld` library (the embedded server), as well as some programs that are useful for application developers.

25.1. libmysqld, the Embedded MySQL Server Library

25.1.1. Overview of the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions:

Function	When to Call
`mysql_server_init()`	Should be called before any other MySQL function is called, preferably early in the `main()` function.
`mysql_server_end()`	Should be called before your program exits.
`mysql_thread_init()`	Should be called in each thread you create that accesses MySQL.
`mysql_thread_end()`	Should be called before calling `pthread_exit()`

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`.

The `mysql_server_`*`xxx`*`()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See Section 25.2.12.1, “`mysql_server_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

25.1.2. Compiling Programs with `libmysqld`

To get a `libmysqld` library you should configure MySQL with the `--with-embedded-server` option. See Section 2.8.2, “Typical `configure` Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into a compiled version of a program, use the GNU C compiler (`gcc`). The compiler will need to know where to find various files and need instructions on how to compile the program. Below is an example of how a program could be compiled from the command-line:

```
gcc mysql_test.c -o mysql_test -lz \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the uncompiled C program file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it's compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` piece is contained in backticks, not single quotes.

25.1.3. Restrictions when using the Embedded MySQL Server

The embedded server has the following limitations:

- No support for `ISAM` tables. (This is mainly done to make the library smaller.)
- No user-defined functions (UDFs).
- No stack trace on core dump.
- No internal RAID support. (This is not normally needed as most current operating systems support big files.)
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

25.1.4. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_server_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_server_init()` function. See Section 25.2.12.1, “`mysql_server_init()`”, for more information on the `mysql_server_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See Section 4.3.2, “Using Option Files”.

25.1.5. Things left to do in Embedded Server (TODO)

- We are going to provide options to leave out some parts of MySQL to make the library smaller.
- There is still a lot of speed optimization to do.
- Errors are written to `stderr`. We will add an option to specify a filename for these.
- We have to change `InnoDB` not to be so verbose when using the embedded version. If your database does not contain `InnoDB` tables, to suppress related messages you can add the `--skip-innodb` option to the options file under the group `[libmysqd_server]`, or when initializing the server with `mysql_server_init()`.

25.1.6. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = { "mysql_test", "--defaults-file=my.cnf" };
int num_elements = sizeof(server_options)/ sizeof(char *);

static char *server_groups[] = { "libmysqld_server", "libmysqld_client" };

int main(void)
{
   mysql_server_init(num_elements, server_options, server_groups);
   mysql = mysql_init(NULL);
   mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
   mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

   mysql_real_connect(mysql, NULL,NULL,NULL, "database1", 0,NULL,0);

   mysql_query(mysql, "SELECT column1, column2 FROM table1");

   results = mysql_store_result(mysql);

   while((record = mysql_fetch_row(results))) {
      printf("%s - %s \n", record[0], record[1]);
   }

   mysql_free_result(results);
   mysql_close(mysql);
   mysql_server_end();

   return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld -lz \
  `/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Example 2

To try out the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

```
test2_libmysqld.c

/*
 * A simple example client, using the embedded MySQL server library
*/

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
  "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
  MYSQL *one, *two;

  /* mysql_server_init() must be called before any other mysql
   * functions.
   *
   * You can use mysql_server_init(0, NULL, NULL), and it
   * initializes the server using groups = {
   *   "server", "embedded", NULL
   *  }.
   *
   * In your $HOME/.my.cnf file, you probably want to put:

[test2_libmysqld_SERVER]
language = /path/to/source/of/mysql/sql/share/english

   * You could, of course, modify argc and argv before passing
   * them to this function.  Or you could create new ones in any
   * way you like.  But all of the arguments in argv (except for
   * argv[0], which is the program name) should be valid options
   * for the MySQL server.
   *
   * If you link this client against the normal mysqlclient
   * library, this function is just a stub that does nothing.
   */
  mysql_server_init(argc, argv, (char **)server_groups);

  one = db_connect("test");
  two = db_connect(NULL);

  db_do_query(one, "SHOW TABLE STATUS");
  db_do_query(two, "SHOW DATABASES");
```

```
  mysql_close(two);
  mysql_close(one);

  /* This must be called after all other mysql functions */
  mysql_server_end();

  exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
  va_list ap;
  va_start(ap, fmt);
  vfprintf(stderr, fmt, ap);
  va_end(ap);
  (void)putc('\n', stderr);
  if (db)
    db_disconnect(db);
  exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
  MYSQL *db = mysql_init(NULL);
  if (!db)
    die(db, "mysql_init failed: no memory");
  /*
   * Notice that the client and server use separate group names.
   * This is critical, because the server does not accept the
   * client's options, and vice versa.
   */
  mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
  if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
    die(db, "mysql_real_connect failed: %s", mysql_error(db));

  return db;
}

void
db_disconnect(MYSQL *db)
{
  mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
  if (mysql_query(db, query) != 0)
    goto err;

  if (mysql_field_count(db) > 0)
  {
    MYSQL_RES   *res;
    MYSQL_ROW    row, end_row;
    int num_fields;

    if (!(res = mysql_store_result(db)))
      goto err;
    num_fields = mysql_num_fields(res);
    while ((row = mysql_fetch_row(res)))
    {
      (void)fputs(">> ", stdout);
      for (end_row = row + num_fields; row < end_row; ++row)
        (void)printf("%s\t", row ? (char*)*row : "NULL");
      (void)fputc('\n', stdout);
    }
    (void)fputc('\n', stdout);
```

```
    mysql_free_result(res);
  }
  else
    (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

  return;

err:
  die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}
```

GNUmakefile

```
# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc      := $(HOME)/mysql-5.1/include
#lib      := $(HOME)/mysql-5.1/libmysqld

CC       := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS   := -g -W -Wall
LDFLAGS  := -static
# You can change -lmysqld to -lmysqlclient to use the
# client/server library
LDLIBS    = -L$(lib) -lmysqld -lz -lm -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
# FreeBSD
LDFLAGS += -pthread
else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
        rm -f $(targets) $(objects) *.core
```

25.1.7. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from MySQL AB. For details, please see http://www.mysql.com/company/legal/licensing/.

25.2. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `clients` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See Chapter 8, *Client and Utility Programs*, for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous queries and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See Section 7.5.2, “Tuning Server Parameters”.

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see Section 25.2.15, “How to Make a Threaded Client”. For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see Section 25.1, “libmysqld, the Embedded MySQL Server Library”.

25.2.1. C API Data types

- `MYSQL`

  This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

  This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

  This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

  This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

  This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

  The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of `0` to `1.84e19`.

  On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

  ```
  printf ("Number of rows: %lu\n", (unsigned long) mysql_num_rows(result));
  ```

The `MYSQL_FIELD` structure contains the members listed here:

- `char * name`

  The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

  The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

  The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the table was given an alias with an `AS` clause, the value of `table` is the alias.

- `char * org_table`

  The name of the table, as a null-terminated string. Aliases are ignored.

- `char * db`

  The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string.

- `char * catalog`

  The catalog name. This value is always `"def"`.

- `char * def`

  The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

  The width of the field, as specified in the table definition.

- `unsigned long max_length`

  The maximum width of the field for the result set (the length of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

- `unsigned int name_length`

  The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

  The length of `table`.

- `unsigned int org_table_length`

  The length of `org_table`.

- `unsigned int db_length`

  The length of `db`.

- `unsigned int catalog_length`

  The length of `catalog`.

- `unsigned int def_length`

  The length of `def`.

- `unsigned int flags`

  Different bit-flags for the field. The `flags` value may have zero or more of the following bits set:

Flag Value	Flag Description
`NOT_NULL_FLAG`	Field can't be `NULL`
`PRI_KEY_FLAG`	Field is part of a primary key
`UNIQUE_KEY_FLAG`	Field is part of a unique key
`MULTIPLE_KEY_FLAG`	Field is part of a non-unique key
`UNSIGNED_FLAG`	Field has the `UNSIGNED` attribute
`ZEROFILL_FLAG`	Field has the `ZEROFILL` attribute
`BINARY_FLAG`	Field has the `BINARY` attribute
`AUTO_INCREMENT_FLAG`	Field has the `AUTO_INCREMENT` attribute
`ENUM_FLAG`	Field is an `ENUM` (deprecated)
`SET_FLAG`	Field is a `SET` (deprecated)
`BLOB_FLAG`	Field is a `BLOB` or `TEXT` (deprecated)
`TIMESTAMP_FLAG`	Field is a `TIMESTAMP` (deprecated)

  Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`, `MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

  The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

  You may use the following convenience macros to determine the boolean status of the `flags` value:

Flag Status	Description
`IS_NOT_NULL(flags)`	True if this field is defined as `NOT NULL`

`IS_PRI_KEY(flags)`	True if this field is a primary key
`IS_BLOB(flags)`	True if this field is a `BLOB` or `TEXT` (deprecated; test `field->type` instead)

- `unsigned int decimals`

  The number of decimals for numeric fields.

- `unsigned int charset_nr`

  The character set number for the field.

- `enum enum_field_types type`

  The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

Type Value	Type Description
`MYSQL_TYPE_TINY`	`TINYINT` field
`MYSQL_TYPE_SHORT`	`SMALLINT` field
`MYSQL_TYPE_LONG`	`INTEGER` field
`MYSQL_TYPE_INT24`	`MEDIUMINT` field
`MYSQL_TYPE_LONGLONG`	`BIGINT` field
`MYSQL_TYPE_DECIMAL`	`DECIMAL` or `NUMERIC` field
`MYSQL_TYPE_NEWDECIMAL`	Precision math `DECIMAL` or `NUMERIC`
`MYSQL_TYPE_FLOAT`	`FLOAT` field
`MYSQL_TYPE_DOUBLE`	`DOUBLE` or `REAL` field
`MYSQL_TYPE_BIT`	`BIT` field
`MYSQL_TYPE_TIMESTAMP`	`TIMESTAMP` field
`MYSQL_TYPE_DATE`	`DATE` field
`MYSQL_TYPE_TIME`	`TIME` field
`MYSQL_TYPE_DATETIME`	`DATETIME` field
`MYSQL_TYPE_YEAR`	`YEAR` field
`MYSQL_TYPE_STRING`	`CHAR` field
`MYSQL_TYPE_VAR_STRING`	`VARCHAR` field
`MYSQL_TYPE_BLOB`	`BLOB` or `TEXT` field (use `max_length` to determine the maximum length)
`MYSQL_TYPE_SET`	`SET` field
`MYSQL_TYPE_ENUM`	`ENUM` field
`MYSQL_TYPE_GEOMETRY`	Spatial field
`MYSQL_TYPE_NULL`	`NULL`-type field
`MYSQL_TYPE_CHAR`	Deprecated; use `MYSQL_TYPE_TINY` instead

  You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

25.2.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See Section 25.2.3, “C API Function Descriptions”.

Function	Description
mysql_affected_rows()	Returns the number of rows changed/deleted/inserted by the last `UPDATE`, `DELETE`, or `INSERT` query.
mysql_autocommit()	Toggles autocommit mode on/off.
mysql_change_user()	Changes user and database on an open connection.
mysql_charset_name()	Returns the name of the default character set for the connection.
mysql_close()	Closes a server connection.
mysql_commit()	Commits the transaction.
mysql_connect()	Connects to a MySQL server. This function is deprecated; use `mysql_real_connect()` instead.
mysql_create_db()	Creates a database. This function is deprecated; use the SQL statement `CREATE DATABASE` instead.
mysql_data_seek()	Seeks to an arbitrary row number in a query result set.
mysql_debug()	Does a `DBUG_PUSH` with the given string.
mysql_drop_db()	Drops a database. This function is deprecated; use the SQL statement `DROP DATABASE` instead.
mysql_dump_debug_info()	Makes the server write debug information to the log.
mysql_eof()	Determines whether the last row of a result set has been read. This function is deprecated; `mysql_errno()` or `mysql_error()` may be used instead.
mysql_errno()	Returns the error number for the most recently invoked MySQL function.
mysql_error()	Returns the error message for the most recently invoked MySQL function.
mysql_escape_string()	Escapes special characters in a string for use in an SQL statement.
mysql_fetch_field()	Returns the type of the next table field.
mysql_fetch_field_direct()	Returns the type of a table field, given a field number.
mysql_fetch_fields()	Returns an array of all field structures.
mysql_fetch_lengths()	Returns the lengths of all columns in the current row.
mysql_fetch_row()	Fetches the next row from the result set.
mysql_field_seek()	Puts the column cursor on a specified column.
mysql_field_count()	Returns the number of result columns for the most recent statement.
mysql_field_tell()	Returns the position of the field cursor used for the last `mysql_fetch_field()`.
mysql_free_result()	Frees memory used by a result set.
mysql_get_client_info()	Returns client version information as a string.
mysql_get_client_version()	Returns client version information as an integer.
mysql_get_host_info()	Returns a string describing the connection.
mysql_get_server_version()	Returns version number of server as an integer.
mysql_get_proto_info()	Returns the protocol version used by the connection.
mysql_get_server_info()	Returns the server version number.
mysql_info()	Returns information about the most recently executed query.
mysql_init()	Gets or initializes a `MYSQL` structure.

mysql_insert_id()	Returns the ID generated for an `AUTO_INCREMENT` column by the previous query.
mysql_kill()	Kills a given thread.
mysql_library_end()	Finalize MySQL C API library.
mysql_library_init()	Initialize MySQL C API library.
mysql_list_dbs()	Returns database names matching a simple regular expression.
mysql_list_fields()	Returns field names matching a simple regular expression.
mysql_list_processes()	Returns a list of the current server threads.
mysql_list_tables()	Returns table names matching a simple regular expression.
mysql_more_results()	Checks whether any more results exist.
mysql_next_result()	Returns/initiates the next result in multiple-statement executions.
mysql_num_fields()	Returns the number of columns in a result set.
mysql_num_rows()	Returns the number of rows in a result set.
mysql_options()	Sets connect options for `mysql_connect()`.
mysql_ping()	Checks whether the connection to the server is working, reconnecting as necessary.
mysql_query()	Executes an SQL query specified as a null-terminated string.
mysql_real_connect()	Connects to a MySQL server.
mysql_real_escape_string()	Escapes special characters in a string for use in an SQL statement, taking into account the current charset of the connection.
mysql_real_query()	Executes an SQL query specified as a counted string.
mysql_refresh()	Flush or reset tables and caches.
mysql_reload()	Tells the server to reload the grant tables.
mysql_rollback()	Rolls back the transaction.
mysql_row_seek()	Seeks to a row offset in a result set, using value returned from `mysql_row_tell()`.
mysql_row_tell()	Returns the row cursor position.
mysql_select_db()	Selects a database.
mysql_server_end()	Finalize embedded server library.
mysql_server_init()	Initialize embedded server library.
mysql_set_server_option()	Sets an option for the connection (like `multi-statements`).
mysql_sqlstate()	Returns the SQLSTATE error code for the last error.
mysql_shutdown()	Shuts down the database server.
mysql_stat()	Returns the server status as a string.
mysql_store_result()	Retrieves a complete result set to the client.
mysql_thread_id()	Returns the current thread ID.
mysql_thread_safe()	Returns 1 if the clients are compiled as thread-safe.
mysql_use_result()	Initiates a row-by-row result set retrieval.
mysql_warning_count()	Returns the warning count for the previous SQL statement.

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. The library can be either the `mysqlclient` C client library or the `mysqld` embedded server library, depending on whether the application was linked with the `-libmysqlclient` or `-libmysqld` flag.

2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling

`mysql_real_connect()`.

3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)

4. Close the connection to the MySQL server by calling `mysql_close()`.

5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

`mysql_library_init()` and `mysql_library_end()` are actually `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL library no matter whether the application uses the `mysqlclient` or `mysqld` library. For older versions of MySQL, you can call `mysql_server_init()` and `mysql_server_end()` instead.

If you like, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the hostname, username, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL queries to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. They should be treated the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that

is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to queries (retrieving rows only as necessary) without knowing whether or not the query is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the query was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the query returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is non-zero, the query should have returned rows, but didn't. This indicates that the query was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

25.2.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or non-zero to indicate an error. Note that “non-zero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                  /* correct */
    ... error ...

if (result < 0)              /* incorrect */
    ... error ...

if (result == -1)            /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

25.2.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

Description

Returns the number of rows changed by the last `UPDATE`, deleted by the last `DELETE` or inserted by the last `INSERT` statement. May be called immediately after `mysql_query()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

Errors

None.

Example

```
mysql_query(&mysql,"UPDATE products SET cost=cost*1.25 WHERE group=10");
printf("%ld products updated",(long) mysql_affected_rows(&mysql));
```

If you specify the flag `CLIENT_FOUND_ROWS` when connecting to `mysqld`, `mysql_affected_rows()` returns the number of rows matched by the `WHERE` statement for `UPDATE` statements.

Note that when you use a `REPLACE` command, `mysql_affected_rows()` returns 2 if the new row replaced an old row, because in this case one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

25.2.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

25.2.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const
char *password, const char *db)
```

Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case the user and database are not changed

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command always performs a `ROLLBACK` of any active transactions, closes all temporary tables, unlocks all locked tables and resets the state as if one had done a new connect. This happens even if the user didn't change.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

- `ER_UNKNOWN_COM_ERROR`

  The MySQL server doesn't implement this command (probably an old server).

- `ER_ACCESS_DENIED_ERROR`

  The user or password was wrong.

- `ER_BAD_DB_ERROR`

  The database didn't exist.

- `ER_DBACCESS_DENIED_ERROR`

  The user did not have access rights to the database.

- `ER_WRONG_DB_NAME`

  The database name was too long.

Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
   fprintf(stderr, "Failed to change user.  Error: %s\n",
           mysql_error(&mysql));
}
```

25.2.3.4. mysql_character_set_name()

```
const char *mysql_character_set_name(MYSQL *mysql)
```

Description

Returns the default character set for the current connection.

Return Values

The default character set

Errors

None.

25.2.3.5. mysql_close()

```
void mysql_close(MYSQL *mysql)
```

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values

None.

Errors

None.

25.2.3.6. mysql_commit()

```
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

25.2.3.7. mysql_connect()

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char
*user, const char *passwd)
```

Description

This function is deprecated. It is preferable to use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

25.2.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

Return Values

Zero if the database was created successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

```
if(mysql_create_db(&mysql, "my_database"))
```

```
{
   fprintf(stderr, "Failed to create new database.  Error: %s\n",
           mysql_error(&mysql));
}
```

25.2.3.9. mysql_data_seek()

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number and should be in the range from `0` to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

None.

Errors

None.

25.2.3.10. mysql_debug()

```
void mysql_debug(const char *debug)
```

Description

Does a `DBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See Section E.1, “Debugging a MySQL Server”, and Section E.2, “Debugging a MySQL Client”.

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:O,/tmp/client.trace");
```

25.2.3.11. mysql_drop_db()

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

Return Values

Zero if the database was dropped successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

```
if(mysql_drop_db(&mysql, "my_database"))
  fprintf(stderr, "Failed to drop the database: Error: %s\n",
          mysql_error(&mysql));
```

25.2.3.12. `mysql_dump_debug_info()`

```
int mysql_dump_debug_info(MYSQL *mysql)
```

Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

Return Values

Zero if the command was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.13. mysql_eof()

```
my_bool mysql_eof(MYSQL_RES *result)
```

Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a non-zero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero if no error occurred. Non-zero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

25.2.3.14. mysql_errno()

```
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, *Error Codes and Messages*.

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

Errors

None.

25.2.3.15. mysql_error()

```
const char *mysql_error(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_errno()`, the following two tests are equivalent:

```
if(mysql_errno(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0] != '\0')
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently you can choose error messages in several different languages. See Section 5.10.2, “Setting the Error Message Language”.

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

25.2.3.16. mysql_escape_string()

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current charset setting.

25.2.3.17. mysql_fetch_field()

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

Errors

None.

Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

25.2.3.18. mysql_fetch_field_direct()

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned
int fieldnr)
```

Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

Return Values

The `MYSQL_FIELD` structure for the specified column.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

25.2.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
   printf("Field %u is %s\n", i, fields[i].name);
}
```

25.2.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). NULL if an error occurred.

Errors

mysql_fetch_lengths() is valid only for the current row of the result set. It returns NULL if you call it before calling mysql_fetch_row() or after retrieving all rows in the result.

Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
         printf("Column %u is %lu bytes in length.\n", i, lengths[i]);
    }
}
```

25.2.3.21. mysql_fetch_row()

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

Description

Retrieves the next row of a result set. When used after mysql_store_result(), mysql_fetch_row() returns NULL when there are no more rows to retrieve. When used after mysql_use_result(), mysql_fetch_row() returns NULL when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by mysql_num_fields(result). If row holds the return value from a call to mysql_fetch_row(), pointers to the values are accessed as row[0] to row[mysql_num_fields(result)-1]. NULL values in the row are indicated by NULL pointers.

The lengths of the field values in the row may be obtained by calling mysql_fetch_lengths(). Empty fields and fields containing NULL both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is NULL, the field is NULL; otherwise, the field is empty.

Return Values

A MYSQL_ROW structure for the next row. NULL if there are no more rows to retrieve or if an error occurred.

Errors

Note that error is not reset between calls to mysql_fetch_row()

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
   unsigned long *lengths;
   lengths = mysql_fetch_lengths(result);
   for(i = 0; i < num_fields; i++)
   {
       printf("[%.*s] ", (int) lengths[i], row[i] ? row[i] : "NULL");
   }
   printf("\n");
}
```

25.2.3.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 25.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result)  // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else  // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
```

```
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

25.2.3.23. `mysql_field_seek()`

```
MYSQL_FIELD_OFFSET       mysql_field_seek(MYSQL_RES       *result,
MYSQL_FIELD_OFFSET offset)
```

Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

Return Values

The previous value of the field cursor.

Errors

None.

25.2.3.24. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

Return Values

The current offset of the field cursor.

Errors

None.

25.2.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

25.2.3.26. mysql_get_character_set_info()

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO
*cs)
```

Description

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

This function was added in MySQL 5.0.10.

Example

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

25.2.3.27. mysql_get_client_info()

```
char *mysql_get_client_info(void)
```

Description

Returns a string that represents the client library version.

Return Values

A character string that represents the MySQL client library version.

Errors

None.

25.2.3.28. mysql_get_client_version()

```
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the client library version. The value has the format XYYZZ where X is the major version, YY is the release level, and ZZ is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

Return Values

An integer that represents the MySQL client library version.

Errors

None.

25.2.3.29. mysql_get_host_info()

```
char *mysql_get_host_info(MYSQL *mysql)
```

Description

Returns a string describing the type of connection in use, including the server hostname.

Return Values

A character string representing the server hostname and the connection type.

Errors

None.

25.2.3.30. mysql_get_proto_info()

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

Description

Returns the protocol version used by current connection.

Return Values

An unsigned integer representing the protocol version used by the current connection.

Errors

None.

25.2.3.31. mysql_get_server_info()

```
char *mysql_get_server_info(MYSQL *mysql)
```

Description

Returns a string that represents the server version number.

Return Values

A character string that represents the server version number.

Errors

None.

25.2.3.32. mysql_get_server_version()

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

Description

Returns the version number of the server as an integer.

Return Values

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.0.12 is returned as 500012.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

Errors

None.

25.2.3.33. `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned
long length)
```

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See Section 9.1.1, “Strings”.

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0x`*`value`* or `X'`*`value`*`'` format. However, the return value does not include the `0x` or `X'...'`. The caller must supply whichever of those is desired.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What's this",11);
end = strmov(end,",0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
   fprintf(stderr, "Failed to insert row, Error: %s\n",
           mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

25.2.3.34. mysql_info()

```
char *mysql_info(MYSQL *mysql)
```

Description

Retrieves a string providing information about the most recently executed query, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of query, as described here. The numbers are illustrative only; the string contains values appropriate for the query.

- `INSERT INTO ... SELECT ...`

  String format: `Records: 100 Duplicates: 0 Warnings: 0`

- `INSERT INTO ... VALUES (...),(...),(...)...`

  String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `LOAD DATA INFILE ...`

  String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`

- `ALTER TABLE`

  String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `UPDATE`

  String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-`NULL` value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

Return Values

A character string representing additional information about the most recently executed query. `NULL` if no information is available for the query.

Errors

None.

25.2.3.35. mysql_init()

```
MYSQL *mysql_init(MYSQL *mysql)
```

Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

Errors

In case of insufficient memory, NULL is returned.

25.2.3.36. mysql_insert_id()

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

Description

Returns the value generated for an AUTO_INCREMENT column by the previous INSERT or UPDATE statement. Use this function after you have performed an INSERT statement into a table that contains an AUTO_INCREMENT field.

More precisely, mysql_insert_id() is updated under these conditions:

- INSERT statements that store a value into an AUTO_INCREMENT column. This is true whether the value is automatically generated by storing the special values NULL or 0 into the column, or is an explicit non-special value.
- In the case of a multiple-row INSERT statement, mysql_insert_id() returns the **first** automatically generated AUTO_INCREMENT value; if no such value is generated, it returns the last **last** explicit value inserted into the AUTO_INCREMENT column.
- INSERT statements that generate an AUTO_INCREMENT value by inserting LAST_INSERT_ID(*expr*) into any column.
- INSERT statements that generate an AUTO_INCREMENT value by updating any column to LAST_INSERT_ID(*expr*).
- The value of mysql_insert_id() is not affected by statements such as SELECT that return a result set.
- If the previous statement returned an error, the value of mysql_insert_id() is undefined.

Note that mysql_insert_id() returns 0 if the previous statement does not use an AUTO_INCREMENT value. If you need to save the value for later, be sure to call mysql_insert_id() immediately after the statement that generates the value.

The value of mysql_insert_id() is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

See Section 12.9.3, “Information Functions”.

Also note that the value of the SQL LAST_INSERT_ID() function always contains the most recently generated AUTO_INCREMENT value, and is not reset between statements because the value of that function is maintained in the server. Another difference is that LAST_INSERT_ID() is not updated if you set an AUTO_INCREMENT column to a specific non-special value.

The reason for the difference between LAST_INSERT_ID() and mysql_insert_id() is that LAST_INSERT_ID() is made easy to use in scripts while mysql_insert_id() tries to provide a little more exact information of what happens to the AUTO_INCREMENT column.

Return Values

Described in the preceding discussion.

Errors

None.

25.2.3.37. mysql_kill()

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

Description

Asks the server to kill the thread specified by `pid`.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.38. `mysql_library_end()`

```
void mysql_library_end(void)
```

Description

This is a synonym for the `mysql_server_end()` function.

See Section 25.2.2, “C API Function Overview”, for usage information.

25.2.3.39. `mysql_library_init()`

```
int mysql_library_init(int argc, char **argv, char **groups)
```

Description

This is a synonym for the `mysql_server_init()` function.

See Section 25.2.2, “C API Function Overview”, for usage information.

25.2.3.40. `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “`%`” or “`_`”, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW databases [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A MYSQL_RES result set for success. NULL if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

- CR_OUT_OF_MEMORY

  Out of memory.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

25.2.3.41. mysql_list_fields()

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const
char *wild)
```

Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the wild parameter. wild may contain the wildcard characters '%' or '_', or may be a NULL pointer to match all fields. Calling mysql_list_fields() is similar to executing the query SHOW COLUMNS FROM *tbl_name* [LIKE *wild*].

Note that it's recommended that you use SHOW COLUMNS FROM *tbl_name* instead of mysql_list_fields().

You must free the result set with mysql_free_result().

Return Values

A MYSQL_RES result set for success. NULL if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.42. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.43. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters "`%`" or "`_`", or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW tables [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.44. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

Description

Returns true if more results exist from the currently executed query, and the application must call `mysql_next_result()` to fetch the results.

Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See Section 25.2.9, “C API Handling of Multiple Query Execution”, and Section 25.2.3.45, “`mysql_next_result()`”.

Errors

None.

25.2.3.45. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

Description

If more query results exist, `mysql_next_result()` reads the next query results and returns the status back to application.

You must call `mysql_free_result()` for the preceding query if it returned a result set.

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next query. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If `mysql_next_result()` returns an error, no other statements are executed and there are no more results to fetch.

See Section 25.2.9, “C API Handling of Multiple Query Execution”.

Return Values

Return Value	Description
0	Successful and there are more results
-1	Successful and there are no more results

>0	An error occurred

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order. For example if you didn't call `mysql_use_result()` for a previous result set.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.46. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether or not the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 25.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
```

```
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result)  // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else  // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
           fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` is = 0. This happens only if something went wrong.

25.2.3.47. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

Return Values

The number of rows in the result set.

Errors

None.

25.2.3.48. `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const
char *arg)
```

Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

`mysql_options()` should be called after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible option values:

Option	Argument Type	Function
MYSQL_INIT_COMMAND	char *	Command to execute when connecting to the MySQL server. Will automatically be re-executed when reconnecting.
MYSQL_OPT_COMPRESS	Not used	Use the compressed client/server protocol.
MYSQL_OPT_CONNECT_TIMEOUT	unsigned int *	Connect timeout in seconds.
MYSQL_OPT_GUESS_CONNECTION	Not used	For an application linked against libmysqld, this allows the library to guess whether to use the embedded server or a remote server. "Guess" means that if the hostname is set and is not localhost, it uses a remote server. This behavior is the default. MYSQL_OPT_USE_EMBEDDED_CONNECTION and MYSQL_OPT_USE_REMOTE_CONNECTION can be used to override it. This option is ignored for applications linked against libmysqlclient.
MYSQL_OPT_LOCAL_INFILE	optional pointer to uint	If no pointer is given or if pointer points to an unsigned int != 0 the command LOAD LOCAL INFILE is enabled.
MYSQL_OPT_NAMED_PIPE	Not used	Use named pipes to connect to a MySQL server on NT.
MYSQL_OPT_PROTOCOL	unsigned int *	Type of protocol to use. Should be one of the enum values of mysql_protocol_type defined in mysql.h.
MYSQL_OPT_READ_TIMEOUT	unsigned int *	Timeout for reads from server (works currently only on Windows on TCP/IP connections).
MYSQL_OPT_RECONNECT	my_bool *	Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect has been off by default since MySQL 5.0.3; this option is new in 5.0.13 and provides a way to set reconnection behavior explicitly.
MYSQL_OPT_SET_CLIENT_IP	char *	For an application linked against linked against libmysqld (with libmysqld compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against libmysqlclient.
MYSQL_OPT_USE_EMBEDDED_CONNECTION	Not used	For an application linked against libmysqld, this forces the use of

		the embedded server for the connection. This option is ignored for applications linked against `libmysqlclient`.
`MYSQL_OPT_USE_REMOTE_CONNECTION`	Not used	For an application linked against `libmysqld`, this forces the use of a remote server for the connection. This option is ignored for applications linked against `libmysqlclient`.
`MYSQL_OPT_USE_RESULT`	Not used	This option is unused.
`MYSQL_OPT_WRITE_TIMEOUT`	`unsigned int *`	Timeout for writes to server (works currently only on Windows on TCP/IP connections).
`MYSQL_READ_DEFAULT_FILE`	`char *`	Read options from the named option file instead of from `my.cnf`.
`MYSQL_READ_DEFAULT_GROUP`	`char *`	Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.
`MYSQL_REPORT_DATA_TRUNCATION`	`my_bool *`	Enable or disable reporting of data truncation errors for prepared statements via `MYSQL_BIND.error`. (Default: disabled.)
`MYSQL_SECURE_AUTH`	`my_bool*`	Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.
`MYSQL_SET_CHARSET_DIR`	`char*`	The pathname to the directory that contains character set definition files.
`MYSQL_SET_CHARSET_NAME`	`char*`	The name of the character set to use as the default character set.
`MYSQL_SHARED_MEMORY_BASE_NAME`	`char*`	Named of shared memory object for communication to server. Should be same as the option `--shared-memory-base-name` used for the `mysqld` server you want to connect to.

Note that the `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options:

Option	Description
`connect-timeout`	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.
`compress`	Use the compressed client/server protocol.
`database`	Connect to this database if no database was specified in the connect command.
`debug`	Debug options.
`disable-local-infile`	Disable use of `LOAD DATA LOCAL`.
`host`	Default hostname.

`init-command`	Command to execute when connecting to MySQL server. Will automatically be re-executed when reconnecting.
`interactive-timeout`	Same as specifying `CLIENT_INTERACTIVE` to `mysql_real_connect()`. See Section 25.2.3.51, “`mysql_real_connect()`”.
`local-in-file[=(0|1)]`	If no argument or argument != 0 then enable use of `LOAD DATA LOCAL`.
`max_allowed_packet`	Max size of packet client can read from server.
`multi-results`	Allow multiple result sets from multiple-statement executions or stored procedures.
`multi-statements`	Allow the client to send multiple statements in a single string (separated by ‘`;`’).
`password`	Default password.
`pipe`	Use named pipes to connect to a MySQL server on NT.
`protocol={TCP | SOCKET | PIPE | MEMORY}`	The protocol to use when connecting to the server.
`port`	Default port number.
`return-found-rows`	Tell `mysql_info()` to return found rows instead of updated rows when using `UPDATE`.
`shared-memory-base-name=`*`na me`*	Shared memory name to use to connect to server (default is "MYSQL").
`socket`	Default socket file.
`user`	Default user.

Note that `timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.1.5-alpha for backward compatibility.

For more information about option files, see Section 4.3.2, “Using Option Files”.

Return Values

Zero for success. Non-zero if you used an unknown option.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_OPT_COMPRESS,0);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"odbc");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
          mysql_error(&mysql));
}
```

This code requests the client to use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

25.2.3.49. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

Description

Checks whether the connection to the server is working. If the connection has gone down, an automatic reconnection is attempted.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

Return Values

Zero if the connection to the server is alive. Non-zero if an error occurred. A non-zero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.50. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *query)
```

Description

Executes the SQL query pointed to by the null-terminated string `query`. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (‘`;`’) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 25.2.9, “C API Handling of Multiple Query Execution”.

`mysql_query()` cannot be used for queries that contain binary data; you should use `mysql_real_query()` instead. (Binary data may contain the ‘`\0`’ character, which `mysql_query()` interprets as the end of the query string.)

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 25.2.3.22, “`mysql_field_count()`”.

Return Values

Zero if the query was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.51. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const
char *user, const char *passwd, const char *db, unsigned int port,
const char *unix_socket, unsigned long client_flag)
```

Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- The first parameter should be the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()` you must call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See Section 25.2.3.48, "`mysql_options()`".
- The value of `host` may be either a hostname or an IP address. If `host` is `NULL` or the string `"localhost"`, a connection to the local host is assumed. If the OS supports sockets (Unix) or named pipes (Windows), they are used instead of TCP/IP to connect to the server.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string `""`, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current username must be specified explicitly. See Section 26.1.9.2, "Configuring a MyODBC DSN on Windows".
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This allows the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether or not they have specified a password.

  Note: Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.
- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe that should be used. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features:

Flag Name	Flag Description
`CLIENT_COMPRESS`	Use compression protocol.
`CLIENT_FOUND_ROWS`	Return the number of found (matched) rows, not the number of affected rows.
`CLIENT_IGNORE_SPACE`	Allow spaces after function names. Makes all functions names re-

	served words.
CLIENT_INTERACTIVE	Allow interactive_timeout seconds (instead of wait_timeout seconds) of inactivity before closing the connection. The client's session wait_timeout variable is set to the value of the session interactive_timeout variable.
CLIENT_LOCAL_FILES	Enable LOAD DATA LOCAL handling.
CLIENT_MULTI_STATEMENTS	Tell the server that the client may send multiple statements in a single string (separated by ';'). If this flag is not set, multiple-statement execution is disabled.
CLIENT_MULTI_RESULTS	Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This is automatically set if CLIENT_MULTI_STATEMENTS is set.
CLIENT_NO_SCHEMA	Don't allow the *db_name.tbl_name.col_name* syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.
CLIENT_ODBC	The client is an ODBC client. This changes mysqld to be more ODBC-friendly.
CLIENT_SSL	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the client library. Instead, use mysql_ssl_set() before calling mysql_real_connect().

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the mysql_real_connect() call. To do this, call mysql_options() with the MYSQL_READ_DEFAULT_FILE or MYSQL_READ_DEFAULT_GROUP option before calling mysql_real_connect(). Then, in the mysql_real_connect() call, specify the "no-value" value for each parameter to be read from an option file:

- For host, specify a value of NULL or the empty string ("").
- For user, specify a value of NULL or the empty string.
- For passwd, specify a value of NULL. (For the password, a value of the empty string in the mysql_real_connect() call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For db, specify a value of NULL or the empty string.
- For port, specify a value of 0.
- For unix_socket, specify a value of NULL.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

Return Values

A MYSQL* connection handle if the connection was successful, NULL if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

Errors

- CR_CONN_HOST_ERROR

Failed to connect to the MySQL server.

- `CR_CONNECTION_ERROR`

  Failed to connect to the local MySQL server.

- `CR_IPSOCK_ERROR`

  Failed to create an IP socket.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SOCKET_CREATE_ERROR`

  Failed to create a Unix socket.

- `CR_UNKNOWN_HOST`

  Failed to find the IP address for the hostname.

- `CR_VERSION_ERROR`

  A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version. This can happen if you use a very old client library to connect to a new server that wasn't started with the `--old-protocol` option.

- `CR_NAMEDPIPEOPEN_ERROR`

  Failed to create a named pipe on Windows.

- `CR_NAMEDPIPEWAIT_ERROR`

  Failed to wait for a named pipe on Windows.

- `CR_NAMEDPIPESETSTATE_ERROR`

  Failed to get a pipe handler on Windows.

- `CR_SERVER_LOST`

  If `connect_timeout` > 0 and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"your_prog_name");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
          mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some non-standard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the

MYSQL structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the MYSQL_OPT_RECONNECT option to mysql_options() to control reconnection behavior.

25.2.3.52. mysql_real_escape_string()

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to,
const char *from, unsigned long length)
```

Note that mysql must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See Section 9.1.1, “Strings”.

The string in from is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in to and a terminating null byte is appended. Characters encoded are NUL (ASCII 0), ‘\n’, ‘\r’, ‘\’, ‘'’, ‘"’, and Control-Z (see Section 9.1, “Literal Values”). (Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. This function quotes the other characters to make them easier to read in log files.)

The string pointed to by from must be length bytes long. You must allocate the to buffer to be at least length*2+1 bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When mysql_real_escape_string() returns, the contents of to is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, you should use the mysql_set_character_set() function rather than executing a SET NAMES (or SET CHARACTER SET) statement. mysql_set_character_set() works like SET NAMES but also affects the character set used by mysql_real_escape_string(), which SET NAMES does not.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\'';
end += mysql_real_escape_string(&mysql, end,"What's this",11);
*end++ = '\'';
*end++ = ',';
*end++ = '\'';
end += mysql_real_escape_string(&mysql, end,"binary data: \0\r\n",16);
*end++ = '\'';
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
   fprintf(stderr, "Failed to insert row, Error: %s\n",
           mysql_error(&mysql));
}
```

The strmov() function used in the example is included in the mysqlclient library and works like strcpy() but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into to, not including the terminating null character.

Errors

None.

25.2.3.53. mysql_real_query()

```
int mysql_real_query(MYSQL *mysql, const char *query, unsigned long
length)
```

Description

Executes the SQL query pointed to by `query`, which should be a string `length` bytes long. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (‘`;`’) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 25.2.9, “C API Handling of Multiple Query Execution”.

You **must** use `mysql_real_query()` rather than `mysql_query()` for queries that contain binary data, because binary data may contain the ‘`\0`’ character. In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the query string.

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 25.2.3.22, “`mysql_field_count()`”.

Return Values

Zero if the query was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.54. mysql_refresh()

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

Description

This functions flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- `REFRESH_GRANT`

Refresh the grant tables, like FLUSH PRIVILEGES.

- REFRESH_LOG

  Flush the logs, like FLUSH LOGS.

- REFRESH_TABLES

  Flush the table cache, like FLUSH TABLES.

- REFRESH_HOSTS

  Flush the host cache, like FLUSH HOSTS.

- REFRESH_STATUS

  Reset status variables, like FLUSH STATUS.

- REFRESH_THREADS

  Flush the thread cache.

- REFRESH_SLAVE

  On a slave replication server, reset the master server information and restart the slave, like RESET SLAVE.

- REFRESH_MASTER

  On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like RESET MASTER.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

25.2.3.55. mysql_reload()

```
int mysql_reload(MYSQL *mysql)
```

Description

Asks the MySQL server to reload the grant tables. The connected user must have the `RELOAD` privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `FLUSH PRIVILEGES` statement instead.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.56. `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

Description

Rolls back the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

25.2.3.57. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET
offset)
```

Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset that should be a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so

`mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

Errors

None.

25.2.3.58. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

You should use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

25.2.3.59. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

25.2.3.60. mysql_set_character_set()

```
int mysql_set_character_set(MYSQL *mysql, char *csname)
```

Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

This function was added in MySQL 5.0.7.

Return Values

Zero for success. Non-zero if an error occurred.

Example

```
MYSQL mysql;

mysql_init(&mysql);
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
          mysql_error(&mysql));
}

if (!mysql_set_charset_name(&mysql, "utf8"))
{
    printf("New client character set: %s\n", mysql_character_set_name(&mysql));
}
```

25.2.3.61. mysql_set_server_option()

```
int        mysql_set_server_option(MYSQL        *mysql,        enum
enum_mysql_set_option option)
```

Description

Enables or disables an option for the connection. `option` can have one of the following values:

MYSQL_OPTION_MULTI_STATEMENTS_ON	Enable multi statement support.
MYSQL_OPTION_MULTI_STATEMENTS_OFF	Disable multi statement support.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- ER_UNKNOWN_COM_ERROR

  The server didn't support mysql_set_server_option() (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

25.2.3.62. mysql_shutdown()

```
int mysql_shutdown(MYSQL *mysql, enum enum_shutdown_level shutdown_level)
```

Description

Asks the database server to shut down. The connected user must have SHUTDOWN privileges. MySQL 5.1 servers support only one type of shutdown; shutdown_level must be equal to SHUTDOWN_DEFAULT. Additional shutdown levels are planned in order to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the libmysqlclient headers and call mysql_shutdown() need to be used with the old libmysqlclient dynamic library.

The shutdown process is described in Section 5.5, “The MySQL Server Shutdown Process”.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

25.2.3.63. mysql_sqlstate()

```
const char *mysql_sqlstate(MYSQL *mysql)
```

Description

Returns a null-terminated string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means “no error.” The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, *Error Codes and Messages*.

Note that not all MySQL errors are mapped to SQLSTATE error codes. The value `'HY000'` (general error) is used for unmapped errors.

Return Values

A null-terminated character string containing the SQLSTATE error code.

See Also

See Section 25.2.3.14, "`mysql_errno()`", Section 25.2.3.15, "`mysql_error()`", and Section 25.2.7.26, "`mysql_stmt_sqlstate()`".

25.2.3.64. `mysql_ssl_set()`

```
int mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert,
const char *ca, const char *capath, const char *cipher)
```

Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless OpenSSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the pathname to the key file.
- `cert` is the pathname to the certificate file.
- `ca` is the pathname to the certificate authority file.
- `capath` is the pathname to a directory that contains trusted SSL CA certificates in pem format.
- `cipher` is a list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

Return Values

This function always returns `0`. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

25.2.3.65. `mysql_stat()`

```
char *mysql_stat(MYSQL *mysql)
```

Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

Return Values

A character string describing the server status. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.66. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth).

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other queries, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect if the query didn't have a result set by checking if `mysql_store_result()` returns 0 (more about this later on).

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 25.2.3.22, “`mysql_field_count()`”.

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the query didn't return a result set (if the query was, for example, an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking if `mysql_error()` returns a non-empty string, if `mysql_errno()` returns non-zero, or if `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

Once you have called `mysql_store_result()` and got a result back that isn't a null pointer, you may call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

You must call `mysql_free_result()` once you are done with the result set.

See Section 25.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

Return Values

A `MYSQL_RES` result structure with the results. `NULL` if an error occurred.

Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.67. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

Return Values

The thread ID of the current connection.

Errors

None.

25.2.3.68. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`).

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which

the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.3.69. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

Description

Returns the number of warnings generated during execution of the previous SQL statement.

Return Values

The warning count.

Errors

None.

25.2.4. C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following statements can be used as prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements. Other statements are not supported in MySQL 5.1.

25.2.5. C API Prepared Statement Data types

Prepared statements mainly use the `MYSQL_STMT` and `MYSQL_BIND` data structures. A third structure, `MYSQL_TIME`, is used to transfer temporal data.

- `MYSQL_STMT`

  This structure represents a prepared statement. A statement is created by calling `mysql_stmt_init()`, which returns a statement handle, that is, a pointer to a `MYSQL_STMT`. The handle is used for all subsequent statement-related functions until you close it with `mysql_stmt_close()`.

  The `MYSQL_STMT` structure has no members that are for application use. Also, you should not try to make a copy of a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

  Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

  This structure is used both for statement input (data values sent to the server) and output (result values returned from the server). For input, it is used with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`. For output, it is used with `mysql_stmt_bind_result()` to bind result set buffers for use in fetching rows with `mysql_stmt_fetch()`.

  The `MYSQL_BIND` structure contains the following members for use by application programs. Each is used both for input and for output, although sometimes for different purposes depending on the direction of data transfer.

  - `enum enum_field_types buffer_type`

    The type of the buffer. The allowable `buffer_type` values are listed later in this section. For input, `buffer_type` indicates what type of value you are binding to a statement parameter. For output, it indicates what type of value you expect to receive in a result buffer.

  - `void *buffer`

    For input, this is a pointer to the buffer in which a statement parameter's data value is stored. For output, it is a pointer to the buffer in which to return a result set column value. For numeric data types, `buffer` should point to a variable of the proper C type. (If you are associ-

ating the variable with a column that has the UNSIGNED attribute, the variable should be an unsigned C type. Indicate whether the variable is signed or unsigned by using the is_unsigned member, described later in this list.) For date and time data types, buffer should point to a MYSQL_TIME structure. For character and binary string data types, buffer should point to a character buffer.

- unsigned long buffer_length

  The actual size of *buffer in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the buffer_length value specifies the length of *buffer when used with mysql_stmt_bind_param(), or the maximum number of data bytes that can be fetched into the buffer when used with mysql_stmt_bind_result().

- unsigned long *length

  A pointer to an unsigned long variable that indicates the actual number of bytes of data stored in *buffer. length is used for character or binary C data. For input parameter data binding, length points to an unsigned long variable that indicates the length of the parameter value stored in *buffer; this is used by mysql_stmt_execute(). For output value binding, mysql_stmt_fetch() places the length of the column value that is returned into the variable that length points to.

  length is ignored for numeric and temporal data types because the length of the data value is determined by the buffer_type value.

- my_bool *is_null

  This member points to a my_bool variable that is true if a value is NULL, false if it is not NULL. For input, set *is_null to true to indicate that you are passing a NULL value as a statement parameter. For output, this value is set to true after you fetch a row if the result set column value returned from the statement is NULL.

  is_null is a pointer to a boolean rather than a boolean scalar so that it can be used in the following way:

  - If your data values are always NULL, use MYSQL_TYPE_NULL to bind the column.
  - If your data values are always NOT NULL, set is_null = (my_bool*) 0.
  - In all other cases, you should set is_null to the address of a my_bool variable and change that variable's value appropriately between executions to indicate whether data values are NULL or NOT NULL.

- my_bool is_unsigned

  This member is used for integer types. (These correspond to the MYSQL_TYPE_TINY, MYSQL_TYPE_SHORT, MYSQL_TYPE_LONG, and MYSQL_TYPE_LONGLONG type codes.) is_unsigned should be set to true for unsigned types and false for signed types.

- my_bool error

  For output, this member is used output to report data truncation errors. Truncation reporting must be enabled by calling mysql_options() with the MYSQL_REPORT_DATA_TRUNCATION option. When enabled, mysql_stmt_fetch() returns MYSQL_DATA_TRUNCATED and error is true in the MYSQL_BIND structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column.

To use a MYSQL_BIND structure, you should zero its contents to initialize it, and then set the members just described appropriately. For example, to declare and initialize an array of three MYSQL_BIND structures, use this code:

```
MYSQL_BIND    bind[3];
memset(bind, 0, sizeof(bind));
```

- `MYSQL_TIME`

  This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. This is done by setting the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types, and setting the `buffer` member to point to a `MYSQL_TIME` structure.

  The `MYSQL_TIME` structure contains the following members:

  - `unsigned int year`

    The year.

  - `unsigned int month`

    The month of the year.

  - `unsigned int day`

    The day of the month.

  - `unsigned int hour`

    The hour of the day.

  - `unsigned int minute`

    The minute of the hour.

  - `unsigned int second`

    The second of the minute.

  - `my_bool neg`

    A boolean flag to indicate whether the time is negative.

  - `unsigned long second_part`

    The fractional part of the second. This member currently is unused.

  Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used: The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See Section 25.2.10, “C API Handling of Date and Time Values”.

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures. The table also shows those SQL types that correspond most closely to each `buffer_type` value, and, for numeric and temporal types, the corresponding C type.

`buffer_type` **Value**	**SQL Type**	**C Type**
`MYSQL_TYPE_TINY`	`TINYINT`	`char`
`MYSQL_TYPE_SHORT`	`SMALLINT`	`short int`
`MYSQL_TYPE_LONG`	`INT`	`int`
`MYSQL_TYPE_LONGLONG`	`BIGINT`	`long long int`
`MYSQL_TYPE_FLOAT`	`FLOAT`	`float`

MYSQL_TYPE_DOUBLE	DOUBLE	double
MYSQL_TYPE_TIME	TIME	MYSQL_TIME
MYSQL_TYPE_DATE	DATE	MYSQL_TIME
MYSQL_TYPE_DATETIME	DATETIME	MYSQL_TIME
MYSQL_TYPE_TIMESTAMP	TIMESTAMP	MYSQL_TIME
MYSQL_TYPE_STRING	CHAR	
MYSQL_TYPE_VAR_STRING	VARCHAR	
MYSQL_TYPE_TINY_BLOB	TINYBLOB/TINYTEXT	
MYSQL_TYPE_BLOB	BLOB/TEXT	
MYSQL_TYPE_MEDIUM_BLOB	MEDIUMBLOB/MEDIUMTEXT	
MYSQL_TYPE_LONG_BLOB	LONGBLOB/LONGTEXT	

Implicit type conversion may be performed in both directions.

25.2.6. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See Section 25.2.7, “C API Prepared Statement Function Descriptions”.

Function	Description
mysql_stmt_affected_rows()	Returns the number of rows changes, deleted, or inserted by prepared UPDATE, DELETE, or INSERT statement.
mysql_stmt_attr_get()	Get value of an attribute for a prepared statement.
mysql_stmt_attr_set()	Sets an attribute for a prepared statement.
mysql_stmt_bind_param()	Associates application data buffers with the parameter markers in a prepared SQL statement.
mysql_stmt_bind_result()	Associates application data buffers with columns in the result set.
mysql_stmt_close()	Frees memory used by prepared statement.
mysql_stmt_data_seek()	Seeks to an arbitrary row number in a statement result set.
mysql_stmt_errno()	Returns the error number for the last statement execution.
mysql_stmt_error()	Returns the error message for the last statement execution.
mysql_stmt_execute()	Executes the prepared statement.
mysql_stmt_fetch()	Fetches the next row of data from the result set and returns data for all bound columns.
mysql_stmt_fetch_column()	Fetch data for one column of the current row of the result set.
mysql_stmt_field_count()	Returns the number of result columns for the most recent statement.
mysql_stmt_free_result()	Free the resources allocated to the statement handle.
mysql_stmt_init()	Allocates memory for MYSQL_STMT structure and initializes it.
mysql_stmt_insert_id()	Returns the ID generated for an AUTO_INCREMENT column by prepared statement.
mysql_stmt_num_rows()	Returns total rows from the statement buffered result set.
mysql_stmt_param_count()	Returns the number of parameters in a prepared SQL statement.
mysql_stmt_param_metadata()	Return parameter metadata in the form of a result set.
mysql_stmt_prepare()	Prepares an SQL string for execution.

mysql_stmt_reset()	Reset the statement buffers in the server.
mysql_stmt_result_metadata()	Returns prepared statement metadata in the form of a result set.
mysql_stmt_row_seek()	Seeks to a row offset in a statement result set, using value returned from `mysql_stmt_row_tell()`.
mysql_stmt_row_tell()	Returns the statement row cursor position.
mysql_stmt_send_long_data()	Sends long data in chunks to server.
mysql_stmt_sqlstate()	Returns the SQLSTATE error code for the last statement execution.
mysql_stmt_store_result()	Retrieves the complete result set to the client.

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare` to prepare it, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

You can also send the text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See Section 25.2.7.25, “`mysql_stmt_send_long_data()`”.

When statement execution has been completed, the statement handle must be closed using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `msyql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.

2. If the statement produces a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.

3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.

4. Call `mysql_stmt_execute()` to execute the statement.

5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.

6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.

7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and total number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the packet row by row and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error code, error message, and SQLSTATE value using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string `"SELECT ?"`.
2. Call `mysql_stmt_bind_param()` to bind the value `3` to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare   [1] SELECT ?
Execute   [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[n]` statement identifier so that you can keep track of which prepared statement is being logged. *n* is a positive integer. If there are multiple prepared statements active simultaneously for the client, *n* may be greater than 1. Each `Execute` lines shows a prepared statement after substitution of data values for ? parameters.

Version notes: `Prepare` lines are displayed without `[n]` before MySQL 4.1.10. `Execute` lines are not displayed at all before MySQL 4.1.10.

25.2.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

Note that all functions operating with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

25.2.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

Description

Returns the total number of rows changed, deleted, or inserted by the last executed statement. May be called immediately after `mysql_stmt_execute()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_stmt_affected_rows()` works like `mysql_num_rows()`.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query, or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_stmt_affected_rows()` was called prior to calling `mysql_stmt_store_result()`. Because `mysql_stmt_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

See Section 25.2.3.1, "`mysql_affected_rows()`", for additional information on the return value.

Errors

None.

Example

For the usage of `mysql_stmt_affected_rows()`, refer to the Example from Section 25.2.7.10, "`mysql_stmt_execute()`".

25.2.7.2. `mysql_stmt_attr_get()`

```
int mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, void *arg)
```

Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that

should contain the option value. If the option is an integer, then `arg` should point to the value of the integer.

See Section 25.2.7.3, "`mysql_stmt_attr_set()`", for a list of options and option types.

Return Values

`0` if okay. Non-zero if `option` is unknown.

Errors

None.

25.2.7.3. `mysql_stmt_attr_set()`

```
int mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, const void *arg)
```

Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible `option` values:

Option	Argument Type	Function
`STMT_ATTR_UPDATE_MAX_LENGTH`	`my_bool *`	If set to 1: Update metadata `MYSQL_FIELD->max_length` in `mysql_stmt_store_result()`.
`STMT_ATTR_CURSOR_TYPE`	`unsigned long *`	Type of cursor to open for statement when `mysql_stmt_execute()` is invoked. `*arg` can be `CURSOR_TYPE_NO_CURSOR` (the default) or `CURSOR_TYPE_READ_ONLY`.
`STMT_ATTR_PREFETCH_ROWS`	`unsigned long *`	Number of rows to fetch from server at a time when using a cursor. `*arg` can be in the range from 1 to the maximum value of `unsigned long`. The default is 1.

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

The `STMT_ATTR_CURSOR_TYPE` option was added in MySQL 5.0.2. The `STMT_ATTR_PREFETCH_ROWS` option was added in MySQL 5.0.6.

Return Values

`0` if okay. Non-zero if `option` is unknown.

Errors

None.

Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                                              (void*) &prefetch_rows);
/* ... check return value ... */
```

25.2.7.4. `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_param()` is used to bind data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each '`?`' parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

The members of each `MYSQL_BIND` element that should be set are described in Section 25.2.5, "C API Prepared Statement Data types".

Return Values

Zero if the bind was successful. Non-zero if an error occurred.

Errors

- `CR_INVALID_BUFFER_USE`

  Indicates if the bind is to supply the long data in chunks and if the buffer type is non string or binary.

- `CR_UNSUPPORTED_PARAM_TYPE`

  The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

For the usage of `mysql_stmt_bind_param()`, refer to the Example from Section 25.2.7.10, “`mysql_stmt_execute()`”.

25.2.7.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_result()` is used to associate (bind) columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol does not place data into the newly bound buffers until the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and the address of the length buffer. The members of each `MYSQL_BIND` element that should be set are described in Section 25.2.5, “C API Prepared Statement Data types”.

Return Values

Zero if the bind was successful. Non-zero if an error occurred.

Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

  The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

For the usage of `mysql_stmt_bind_result()`, refer to the Example from Section 25.2.7.11, “`mysql_stmt_fetch()`”.

25.2.7.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

Return Values

Zero if the statement was freed successfully. Non-zero if an error occurred.

Errors

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

For the usage of `mysql_stmt_close()`, refer to the Example from Section 25.2.7.10, “`mysql_stmt_execute()`”.

25.2.7.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from `0` to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

None.

Errors

None.

25.2.7.8. `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, *Error Codes and Messages*.

Return Values

An error code value. Zero if no error occurred.

Errors

None.

25.2.7.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (`""`) is returned if no error occurred. This means the following two tests are equivalent:

```
if (mysql_stmt_errno(stmt))
{
  // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
  // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently you can choose error messages in several different languages.

Return Values

A character string that describes the error. An empty string if no error occurred.

Errors

None.

25.2.7.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

If the statement is an `UPDATE`, `DELETE`, or `INSERT`, the total number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`. If this is a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to Section 25.2.7.11, “`mysql_stmt_fetch()`”.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

Return Values

Zero if execution was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\
                                                     col2 VARCHAR(40),\
                                                     col3 SMALLINT,\
                                                     col4 TIMESTAMP)"
#define INSERT_SAMPLE "INSERT INTO test_table(col1,col2,col3) VALUES(?,?,?)"

MYSQL_STMT    *stmt;
MYSQL_BIND    bind[3];
my_ulonglong  affected_rows;
int           param_count;
short         small_data;
int           int_data;
char          str_data[STRING_SIZE];
unsigned long str_length;
my_bool       is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
  fprintf(stderr, " DROP TABLE failed\n");
  fprintf(stderr, " %s\n", mysql_error(mysql));
  exit(0);
}
```

```
if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
  fprintf(stderr, " CREATE TABLE failed\n");
  fprintf(stderr, " %s\n", mysql_error(mysql));
  exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/*  sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
  fprintf(stderr, " mysql_stmt_init(), out of memory\n");
  exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
  fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}
fprintf(stdout, " prepare, INSERT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d\n", param_count);

if (param_count != 3) /* validate parameter count */
{
  fprintf(stderr, " invalid parameter count returned by MySQL\n");
  exit(0);
}

/* Bind the data for all 3 parameters */

memset(bind, 0, sizeof(bind));

/* INTEGER PARAM */
/* This is a number type, so there is no need to specify buffer_length */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= 0;
bind[0].length= 0;

/* STRING PARAM */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= 0;
bind[1].length= &str_length;

/* SMALLINT PARAM */
bind[2].buffer_type= MYSQL_TYPE_SHORT;
bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null;
bind[2].length= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
  fprintf(stderr, " mysql_stmt_bind_param() failed\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}

/* Specify the data values for the first row */
int_data= 10;             /* integer */
```

```
strncpy(str_data, "MySQL", STRING_SIZE); /* string  */
str_length= strlen(str_data);

/* INSERT SMALLINT data as NULL */
is_null= 1;

/* Execute the INSERT statement - 1*/
if (mysql_stmt_execute(stmt))
{
  fprintf(stderr, " mysql_stmt_execute(), 1 failed\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}

/* Get the total number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
                (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
  fprintf(stderr, " invalid affected rows by MySQL\n");
  exit(0);
}

/* Specify data values for second row, then re-execute the statement */
int_data= 1000;
strncpy(str_data, "The most popular Open Source database", STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000;         /* smallint */
is_null= 0;               /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
  fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
                (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
  fprintf(stderr, " invalid affected rows by MySQL\n");
  exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
  fprintf(stderr, " failed while closing the statement\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}
```

Note: For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the BitKeeper source repository.

25.2.7.11. `mysql_stmt_fetch()`

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists, that is, after a call to `mysql_stmt_execute()` that creates a result set or after `mysql_stmt_store_result()`, which is called after `mysql_stmt_execute()` to buffer the entire result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer.

All columns must be bound by the application before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains TRUE (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

Type	Length
MYSQL_TYPE_TINY	1
MYSQL_TYPE_SHORT	2
MYSQL_TYPE_LONG	4
MYSQL_TYPE_LONGLONG	8
MYSQL_TYPE_FLOAT	4
MYSQL_TYPE_DOUBLE	8
MYSQL_TYPE_TIME	sizeof(MYSQL_TIME)
MYSQL_TYPE_DATE	sizeof(MYSQL_TIME)
MYSQL_TYPE_DATETIME	sizeof(MYSQL_TIME)
MYSQL_TYPE_STRING	data length
MYSQL_TYPE_BLOB	data_length

Return Values

Return Value	Description
0	Successful, the data has been fetched to application data buffers.
1	Error occurred. Error code and message can be obtained by calling `mysql_stmt_errno()` and `mysql_stmt_error()`.
MYSQL_NO_DATA	No more rows/data exists
MYSQL_DATA_TRUNCATED	Data truncation occurred

`MYSQL_DATA_TRUNCATED` is not returned unless truncation reporting is enabled with `mysql_options()`. To determine which parameters were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` parameter structures.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

- `CR_UNSUPPORTED_PARAM_TYPE`

  The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.

- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in Section 25.2.7.10, "`mysql_stmt_execute()`".) The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 FROM test_table"

MYSQL_STMT    *stmt;
MYSQL_BIND    bind[4];
MYSQL_RES     *prepare_meta_result;
MYSQL_TIME    ts;
unsigned long length[4];
int           param_count, column_count, row_count;
short         small_data;
int           int_data;
char          str_data[STRING_SIZE];
my_bool       is_null[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{

    fprintf(stdout, " %d(%ld)\n", small_data, length[2]);

  /* column 4 */
  fprintf(stdout, "   column4 (timestamp): ");
  if (is_null[3])
    fprintf(stdout, " NULL\n");
  else
    fprintf(stdout, " %04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
                    ts.year, ts.month, ts.day,
                    ts.hour, ts.minute, ts.second,
                    length[3]);
  fprintf(stdout, "\n");
}

/* Validate rows fetched */
fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
  fprintf(stderr, " MySQL failed to return all rows\n");
  exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
  fprintf(stderr, " failed while closing the statement\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}
```

25.2.7.12. mysql_stmt_fetch_column()

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, un-
signed int column, unsigned long offset)
```

Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

Return Values

Zero if the value was fetched successfully. Non-zero if an error occurred.

Errors

- `CR_INVALID_PARAMETER_NO`

  Invalid column number.

- `CR_NO_DATA`

  The end of the result set has already been reached.

25.2.7.13. mysql_stmt_field_count()

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

25.2.7.14. mysql_stmt_free_result()

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

Return Values

Zero if the result set was freed successfully. Non-zero if an error occurred.

Errors

25.2.7.15. mysql_stmt_init()

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

Description

Create a MYSQL_STMT handle. The handle should be freed with mysql_stmt_close(MYSQL_STMT *).

Return values

A pointer to a MYSQL_STMT structure in case of success. NULL if out of memory.

Errors

- CR_OUT_OF_MEMORY

  Out of memory.

25.2.7.16. mysql_stmt_insert_id()

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

Description

Returns the value generated for an AUTO_INCREMENT column by the prepared INSERT or UPDATE statement. Use this function after you have executed a prepared INSERT statement on a table which contains an AUTO_INCREMENT field.

See Section 25.2.3.36, "mysql_insert_id()", for more information.

Return Values

Value for AUTO_INCREMENT column which was automatically generated or explicitly set during execution of prepared statement, or value generated by LAST_INSERT_ID(*expr*) function. Return value is undefined if statement does not set AUTO_INCREMENT value.

Errors

None.

25.2.7.17. mysql_stmt_num_rows()

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

Description

Returns the number of rows in the result set.

The use of mysql_stmt_num_rows() depends on whether or not you used mysql_stmt_store_result() to buffer the entire result set in the statement handle.

If you use mysql_stmt_store_result(), mysql_stmt_num_rows() may be called immediately.

Return Values

The number of rows in the result set.

Errors

None.

25.2.7.18. mysql_stmt_param_count()

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

Description

Returns the number of parameter markers present in the prepared statement.

Return Values

An unsigned long integer representing the number of parameters in a statement.

Errors

None.

Example

For the usage of `mysql_stmt_param_count()`, refer to the Example from Section 25.2.7.10, “`mysql_stmt_execute()`”.

25.2.7.19. mysql_stmt_param_metadata()

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

Description

Return Values

Errors

25.2.7.20. mysql_stmt_prepare()

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *query, unsigned long length)
```

Description

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `query` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (‘`;`’) or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (‘`?`’) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not allowed for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Return Values

Zero if the statement was prepared successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns non-zero), the error message can be obtained by calling `mysql_stmt_error()`.

Example

For the usage of `mysql_stmt_prepare()`, refer to the Example from Section 25.2.7.10, “`mysql_stmt_execute()`”.

25.2.7.21. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

Description

Reset the prepared statement on the client and server to state after prepare. This is mainly used to reset data sent with `mysql_stmt_send_long_data()`. Any open cursor for the statement is closed.

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

Return Values

Zero if the statement was reset successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query

- CR_UNKNOWN_ERROR

  An unknown error occurred.

25.2.7.22. mysql_stmt_result_metadata()

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

Description

If a statement passed to mysql_stmt_prepare() is one that produces a result set, mysql_stmt_result_metadata() returns the result set metadata in the form of a pointer to a MYSQL_RES structure that can be used to process the meta information such as total number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- mysql_num_fields()
- mysql_fetch_field()
- mysql_fetch_field_direct()
- mysql_fetch_fields()
- mysql_field_count()
- mysql_field_seek()
- mysql_field_tell()
- mysql_free_result()

The result set structure should be freed when you are done with it, which you can do by passing it to mysql_free_result(). This is similar to the way you free a result set obtained from a call to mysql_store_result().

The result set returned by mysql_stmt_result_metadata() contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with mysql_stmt_fetch().

Return Values

A MYSQL_RES result structure. NULL if no meta information exists for the prepared query.

Errors

- CR_OUT_OF_MEMORY

  Out of memory.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

Example

For the usage of mysql_stmt_result_metadata(), refer to the Example from Section 25.2.7.11, “mysql_stmt_fetch()”.

25.2.7.23. mysql_stmt_row_seek()

```
MYSQL_ROW_OFFSET        mysql_stmt_row_seek(MYSQL_STMT        *stmt,
MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

Errors

None.

25.2.7.24. mysql_stmt_row_tell()

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

25.2.7.25. mysql_stmt_send_long_data()

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int
parameter_number, const char *data, unsigned long length)
```

Description

Allows an application to send parameter data to the server in pieces (or "chunks"). This function can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

Note: The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See Section 25.2.7.21, “`mysql_stmt_reset()`”.

Return Values

Zero if the data is sent successfully to server. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

The following example demonstrates how to send the data for a `TEXT` column in chunks. It inserts the data value `'MySQL - The most popular Open Source database'` into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long       length;

smtt = mysql_stmt_init(mysql);
if (!stmt)
{
  fprintf(stderr, " mysql_stmt_init(), out of memory\n");
  exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
  fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
  fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
  exit(0);
}
 memset(bind, 0, sizeof(bind));
 bind[0].buffer_type= MYSQL_TYPE_STRING;
 bind[0].length= &length;
 bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
  fprintf(stderr, "\n param bind failed");
  fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
  exit(0);
}

 /* Supply data in chunks to server */
 if (!mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
  fprintf(stderr, "\n send_long_data failed");
```

```
  fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
  exit(0);
}

 /* Supply the next piece of data */
 if (mysql_stmt_send_long_data(stmt,0," - The most popular Open Source database
{
  fprintf(stderr, "\n send_long_data failed");
  fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
  exit(0);
}

 /* Now, execute the query */
 if (mysql_stmt_execute(stmt))
{
  fprintf(stderr, "\n mysql_stmt_execute failed");
  fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
  exit(0);
}
```

25.2.7.26. mysql_stmt_sqlstate()

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. `"00000"` means “no error”. The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, *Error Codes and Messages*.

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value `"HY000"` (general error) is used for unmapped errors.

Return Values

A null-terminated character string containing the SQLSTATE error code.

25.2.7.27. mysql_stmt_store_result()

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

Description

You must call `mysql_stmt_store_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`), and only if you want to buffer the complete result set by the client, so that the subsequent `mysql_stmt_fetch()` call returns buffered data.

It is unnecessary to call `mysql_stmt_store_result()` for other statements, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to Section 25.2.7.22, “`mysql_stmt_result_metadata()`”.

Note: MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications doesn't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See Section 25.2.7.3, “`mysql_stmt_attr_set()`”.

Return Values

Zero if the results are buffered successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

  Out of memory.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

25.2.8. C API Prepared statement problems

Here follows a list of the currently known problems with prepared statements:

- `TIME`, `TIMESTAMP`, and `DATETIME` do not support parts of seconds (for example from `DATE_FORMAT()`.

- When converting an integer to string, `ZEROFILL` is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with `MIN(number-with-zerofill)`).

- When converting a floating point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.

- *Prepared statements do not use the Query Cache, even in cases where a query does not contain any placeholders.* See Section 5.13.1, “How the Query Cache Operates”.

25.2.9. C API Handling of Multiple Query Execution

MySQL 5.1 supports the execution of multiple statements specified in a single query string. To use this capability with a given connection, you must specify the `CLIENT_MULTI_STATEMENTS` option in the `flags` parameter to `mysql_real_connect()` when opening the connection. You can also set this for an existing connection by calling `mysql_set_server_option(MYSQL_OPTION_MULTI_STATEMENTS_ON)`.

By default, `mysql_query()` and `mysql_real_query()` return only the first query status and the subsequent queries status can be processed using `mysql_more_results()` and `mysql_next_result()`.

```
/* Connect to server with option CLIENT_MULTI_STATEMENTS */
mysql_real_connect(..., CLIENT_MULTI_STATEMENTS);

/* Now execute multiple queries */
mysql_query(mysql,"DROP TABLE IF EXISTS test_table;\
                   CREATE TABLE test_table(id INT);\
```

```
                  INSERT INTO test_table VALUES(10);\
                  UPDATE test_table SET id=20 WHERE id=10;\
                  SELECT * FROM test_table;\
                  DROP TABLE test_table");
do
{
  /* Process all results */
  ...
  printf("total affected rows: %lld", mysql_affected_rows(mysql));
  ...
  if (!(result= mysql_store_result(mysql)))
  {
     printf(stderr, "Got fatal error processing query\n");
     exit(1);
  }
  process_result_set(result); /* client function */
  mysql_free_result(result);
} while (!mysql_next_result(mysql));
```

The multiple-statement capability can be used with `mysql_query()` or `mysql_real_query()`. It cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement.

25.2.10. C API Handling of Date and Time Values

The binary protocol allows you to send and receive date and time values (`DATE`, `TIME`, `DATETIME`, and `TIMESTAMP`), using the `MYSQL_TIME` structure. The members of this structure are described in Section 25.2.5, “C API Prepared Statement Data types”.

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.

2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.

3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to be passed.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_bind_results()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```
  MYSQL_TIME  ts;
  MYSQL_BIND  bind[3];
  MYSQL_STMT  *stmt;
```

```
strmov(query, "INSERT INTO test_table(date_field, time_field,
                                      timestamp_field) VALUES(?,?,?");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
  fprintf(stderr, " mysql_stmt_init(), out of memory\n");
  exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
  fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
  fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
  exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
..
```

25.2.11. C API Threaded Function Descriptions

You need to use the following functions when you want to create a threaded client. See Section 25.2.15, “How to Make a Threaded Client”.

25.2.11.1. `my_init()`

```
void my_init(void)
```

Description

This function needs to be called once in the program before calling any MySQL function. This initializes some global variables that MySQL needs. If you are using a thread-safe client library, this also calls `mysql_thread_init()` for this thread.

This is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()` and `mysql_connect()`.

Return Values

None.

25.2.11.2. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

Description

This function needs to be called for each created thread to initialize thread-specific variables.

This is automatically called by `my_init()` and `mysql_connect()`.

Return Values

Zero if successful. Non-zero if an error occurred.

25.2.11.3. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

Note that this function *is not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

Return Values

None.

25.2.11.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

Description

This function indicates whether the client is compiled as thread-safe.

Return Values

1 if the client is thread-safe, 0 otherwise.

25.2.12. C API Embedded Server Function Descriptions

If you want to allow your application to be linked against the embedded MySQL server library, you must use the `mysql_server_init()` and `mysql_server_end()` functions. See Section 25.1, “libmysqld, the Embedded MySQL Server Library”.

However, to provide improved memory management, even programs that are linked with `-lmysqlclient` rather than `-lmysqld` should include calls to begin and end use of the library. The `mysql_library_init()` and `mysql_library_end()` functions can be used to do this. These actually are `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses `libmysqlclient` or `libmysqld`. For more information, see Section 25.2.2, “C API Function Overview”.

25.2.12.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

Description

This function **must** be called once in the program using the embedded server before calling any other MySQL function. It starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses. If this function is not called, the next call to `mysql_init()` executes `mysql_server_init()`. If you are using the DBUG package that comes with MySQL, you should call this after you have called `my_init()`.

The `argc` and `argv` arguments are analogous to the arguments to `main()`. The first element of `argv` is ignored (it typically contains the program name). For convenience, `argc` may be `0` (zero) if there are no command-line arguments for the server. `mysql_server_init()` makes a copy of the arguments so it's safe to destroy `argv` or `groups` after the call.

If you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `NULL`-terminated list of strings in `groups` selects which groups in the option files are active. See Section 4.3.2, “Using Option Files”. For convenience, `groups` may be `NULL`, in which case the `[server]` and `[embedded]` groups are active.

Example

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
  "this_program",       /* this string is not used */
  "--datadir=.",
  "--key_buffer_size=32M"
};
static char *server_groups[] = {
  "embedded",
  "server",
  "this_program_SERVER",
  (char *)NULL
};

int main(void) {
  if (mysql_server_init(sizeof(server_args) / sizeof(char *),
                        server_args, server_groups))
    exit(1);

  /* Use any MySQL API functions here */

  mysql_server_end();

  return EXIT_SUCCESS;
}
```

Return Values

0 if okay, 1 if an error occurred.

25.2.12.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

Description

This function **must** be called once in the program after all other MySQL functions. It shuts down the embedded server.

Return Values

None.

25.2.13. Common questions and problems when using the C API

25.2.13.1. Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data couldn't be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a non-empty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a non-zero value, the statement should have produced a non-empty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

25.2.13.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

  For a fast recreate, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.

- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See Section 25.2.3.36, “`mysql_insert_id()`”.

- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

25.2.13.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
```

```
    used_id = mysql_insert_id(&mysql);
}
```

For more information, see Section 25.2.3.36, “`mysql_insert_id()`”.

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a non-magic value (that is, a value that is not `NULL` and not `0`).

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
    VALUES(NULL,'text');              # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
    VALUES(LAST_INSERT_ID(),'text');  # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

25.2.13.4. Problems Linking with the C API

When linking with the C API, the following errors may occur on some systems:

```
gcc -g -o client test.o -L/usr/local/lib/mysql -lmysqlclient -lsocket -lnsl

Undefined        first referenced
 symbol          in file
floor            /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client
```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

25.2.14. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` in the link command.

For clients that use MySQL header files, you may need to specify an `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so that the compiler can find the header files.

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See Section 25.9.2, “mysql_config — Get Compile Options for Compiling Clients”.

You can use it to compile a MySQL client as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname `$CFG --cflags` progname.c `$CFG --libs`"
```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

25.2.15. How to Make a Threaded Client

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, the socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_server_init`(), `mysql_init()`, or `mysql_connect()`. If you want to use your own `SIGPIPE` handler, you should first call `mysql_server_init()` and then install your handler.

In the older binaries we distribute on our Web site (http://www.mysql.com/), the client libraries are not normally compiled with the thread-safe option (the Windows binaries are by default compiled to be thread-safe). Newer binary distributions should have both a normal and a thread-safe client library.

To get a threaded client where you can interrupt the client from other threads and set timeouts when talking with the MySQL server, you should use the `-lmysys`, `-lmystrings`, and `-ldbug` libraries and the `net_serv.o` code that the server uses.

If you don't need interrupts or timeouts, you can just compile a thread-safe client library (`mysqlclient_r`) and use this. See Section 25.2, “MySQL C API”. In this case, you don't have to worry about the `net_serv.o` object file or the other MySQL libraries.

When using a threaded client and you want to use timeouts and interrupts, you can make great use of the routines in the `thr_alarm.c` file. If you are using routines from the `mysys` library, the only thing you must remember is to call `my_init()` first! See Section 25.2.11, “C API Threaded Function Descriptions”.

All functions except `mysql_real_connect()` are by default thread-safe. The following notes describe how to compile a thread-safe client library and use it in a thread-safe manner. (The notes below for `mysql_real_connect()` actually apply to `mysql_connect()` as well, but because `mysql_connect()` is deprecated, you should be using `mysql_real_connect()` anyway.)

To make `mysql_real_connect()` thread-safe, you must recompile the client library with this command:

```
shell> ./configure --enable-thread-safe-client
```

This creates a thread-safe client library `libmysqlclient_r`. (Assuming that your OS has a thread-safe `gethostbyname_r()` function.) This library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Two threads can't send a query to the MySQL server at the same time on the same connection. In particular, you have to ensure that between a `mysql_query()` and `mysql_store_result()` no other thread is using the same connection.
- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- If you use `mysql_use_result`, you have to ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.
- If you want to use multiple threads on the same connection, you must have a mutex lock around your `mysql_query()` and `mysql_store_result()` call combination. Once `mysql_store_result()` is ready, the lock can be released and other threads may query the

same connection.

- If you program with POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

You need to know the following if you have a thread that is calling MySQL functions which did not create the connection to the MySQL database:

When you call `mysql_init()` or `mysql_connect()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things).

If you call a MySQL function, before the thread has called `mysql_init()` or `mysql_connect()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later.

To get things to work smoothly you have to do the following:

1. Call `my_init()` at the start of your program if it calls any other MySQL function before calling `mysql_real_connect()`.
2. Call `mysql_thread_init()` in the thread handler before calling any MySQL function.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

You may get some errors because of undefined symbols when linking your client with `libmysqlclient_r`. In most cases this is because you haven't included the thread libraries on the link/compile line.

25.3. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with the Apache Web server.

PHP actually provides two different MySQL API extensions:

- `mysql`: Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 5.1, nor does it support prepared statements or multiple statements. If you wish to use this extension with MySQL 5.1, you will likely want to configure the MySQL server to use the `--old-passwords` option (see Section A.2.3, "`Client does not support authentication protocol`"). This extension is documented on the PHP Web site at http://php.net/mysql.
- `mysqli` - Stands for "MySQL, Improved"; this extension is available only in PHP 5. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 5.1, as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface. You can read the documentation for the `mysqli` extension at http://php.net/mysqli. A helpful article can be found at http://www.zend.com/php5/articles/php5-mysqli.php.

The PHP distribution and documentation are available from the PHP Web site [http://www.php.net/].

25.3.1. Common Problems with MySQL and PHP

- `Error: Maximum Execution Time Exceeded`: This is a PHP limit; go into the `php.ini` file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.

- `Fatal error: Call to unsupported or undefined function mysql_connect() in ...`: This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This process is described in detail in the PHP manual.

- `Error: Undefined reference to 'uncompress'`: This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.

- `Error: Client does not support authentication protocol`: This is most often encountered when trying to use the older `mysql` extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer `mysqli` extension; or configure the MySQL server with `--old-passwords`. (See Section A.2.3, "`Client does not support authentication protocol`", for more information.)

Those with PHP4 legacy code can make use of a compatibility layer for the old and new MySQL libraries, such as this one: http://www.coggeshall.org/oss/mysql2i.

25.4. MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

Installation instructions for Perl DBI support are given in Section 2.13, "Perl Installation Notes".

DBI information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

  ```
  shell> perldoc DBI
  shell> perldoc DBI::FAQ
  shell> perldoc DBD::mysql
  ```

  You can also use `pod2man`, `pod2html`, and so forth to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, http://dbi.perl.org/. That site hosts a general DBI mailing list. MySQL AB hosts a list specifically about `DBD::mysql`; see Section 1.7.1, "MySQL Mailing Lists".

- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, http://dbi.perl.org/.

  For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is http://www.kitebird.com/mysql-perl/.

25.5. MySQL C++ API

`MySQL++` is a MySQL API for C++. Warren Young has taken over this project. More information can be found at http://www.mysql.com/products/mysql++/.

25.5.1. Borland C++

You can compile the MySQL Windows source with Borland C++ 5.02. (The Windows source includes only projects for Microsoft VC++, for Borland C++ you have to do the project files yourself.)

One known problem with Borland C++ is that it uses a different structure alignment than VC++. This means that you run into problems if you try to use the default `libmysql.dll` libraries (that were compiled using VC++) with Borland C++. To avoid this problem, only call `mysql_init()` with `NULL` as an argument, not a pre-allocated `MYSQL` structure.

25.6. MySQL Python API

`MySQLdb` provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at http://sourceforge.net/projects/mysql-python/.

25.7. MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at http://www.xdobry.de/mysqltcl/.

25.8. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at http://efsa.sourceforge.net/archive/ravits/mysql.htm.

25.9. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

- `msql2mysql`

  A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting.

- `mysql_config`

  A shell script that produces the option values needed when compiling MySQL programs.

25.9.1. msql2mysql — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
```

```
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See Section 8.15, “replace — A String-Replacement Utility”.

25.9.2. mysql_config — Get Compile Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL.

`mysql_config` supports the following options:

- `--cflags`

  Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library.

- `--include`

  Compiler options to find MySQL include files. (Note that normally you would use `--cflags` instead of this option.)

- `--libmysqld-libs`, `---embedded`

  Libraries and options required to link with the MySQL embedded server.

- `--libs`

  Libraries and options required to link with the MySQL client library.

- `--libs_r`

  Libraries and options required to link with the thread-safe MySQL client library.

- `--port`

  The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

  The default Unix socket file, defined when configuring MySQL.

- `--version`

  Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include        [-I/usr/local/mysql/include/mysql]
  --libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz
                    -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]
  --libs_r         [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                    -lpthread -lz -lcrypt -lnsl -lm -lpthread]
```

```
  --socket         [/tmp/mysql.sock]
  --port           [3306]
  --version        [4.0.16]
  --libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
                    -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use `mysql_config` within a command line to include the value that it displays for a particular option. For example, to compile a MySQL client program, use `mysql_config` as follows:

```
shell> CFG=/usr/local/mysql/bin/mysql_config
shell> sh -c "gcc -o progname `$CFG --cflags` progname.c `$CFG --libs`"
```

When you use `mysql_config` this way, be sure to invoke it within backtick (‘``’) characters. That tells the shell to execute it and substitute its output into the surrounding command.

Chapter 26. Connectors

This chapter describes MySQL Connectors, drivers that provide connectivity to the MySQL server for client programs.

26.1. MySQL Connector/ODBC

MySQL provides support for ODBC by means of MySQL Connector/ODBC, the family of MyODBC drivers. This is the reference for the Connector/ODBC product family of MyODBC drivers that provide ODBC 3.5x compliant access to the MySQL Database System. It teaches you how to install MyODBC and how to use it. There is also information about common programs that are known to work with MyODBC and answers to some of the most frequently asked questions about MyODBC.

This reference applies to MyODBC 3.51. You can find a manual for an older version of MyODBC in the binary or source distribution for that version.

This is a reference to the MySQL ODBC drivers, not a general ODBC reference. For more information about ODBC, refer to http://www.microsoft.com/data/.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to http://dev.mysql.com/doc/.

If you have questions that are not answered in this document, please send a mail message to <myodbc@lists.mysql.com>.

26.1.1. Introduction to MyODBC

26.1.1.1. What is ODBC?

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to http://www.microsoft.com/data/.

26.1.1.2. What is Connector/ODBC?

Connector/ODBC is the term designating the MySQL AB product family of MySQL ODBC drivers. These are known as the MyODBC drivers.

26.1.1.3. What is MyODBC 2.50?

MyODBC 2.50 is a 32-bit ODBC driver from MySQL AB that is based on ODBC 2.50 specification level 0 (with level 1 and 2 features). This is one of the most popular ODBC drivers in the Open Source market, used by many users to access the MySQL functionality.

26.1.1.4. What is MyODBC 3.51?

MyODBC 3.51 is a 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. This version is enhanced compared to the existing MyODBC 2.50 driver. It has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

26.1.1.5. Where to Get MyODBC

MySQL AB distributes all its products under the General Public License (GPL). You can get a copy of the latest version of MyODBC binaries and sources from the MySQL AB Web site http://dev.mysql.com/downloads/.

For more information about MyODBC, visit http://www.mysql.com/products/myodbc/.

For more information about licensing, visit http://www.mysql.com/company/legal/licensing/.

26.1.1.6. Supported Platforms

MyODBC can be used on all major platforms supported by MySQL, such as:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix Operating Systems
  - AIX
  - Amiga
  - BSDI
  - DEC
  - FreeBSD
  - HP-UX 10, 11
  - Linux
  - Mac OS X Server
  - Mac OS X
  - NetBSD
  - OpenBSD
  - OS/2
  - SGI Irix
  - Solaris
  - SunOS
  - SCO OpenServer
  - SCO UnixWare
  - Tru64 Unix

If a binary distribution is not available for downloading for a particular platform, you can build the driver yourself by downloading the driver sources. You can contribute the binaries to MySQL by sending a mail message to <myodbc@lists.mysql.com>, so that it becomes available for other users.

26.1.1.7. MyODBC Mailing List

MySQL AB provides assistance to the user community by means of its mailing lists. For MyODBC-related issues, you can get help from experienced users by using the <myodbc@lists.mysql.com> mailing list.

For information about subscribing to MySQL mailing lists or to browse list archives, visit http://lists.mysql.com/. See Section 1.7.1, “MySQL Mailing Lists”.

Of particular interest is the ODBC forum in the MySQL Connectors section of the forums.

26.1.1.8. MyODBC Forum

Community support from experienced users is available through the MySQL Forums, located at http://forums.mysql.com. See Section 1.7.2, “MySQL Community Support at the MySQL Forums”.

26.1.1.9. How to Report MyODBC Problems or Bugs

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the `ODBC Manager` (the log you get when requesting logs from `ODBC ADMIN`) and MyODBC. The procedure for doing this is described in Section 26.1.9.7, “Getting an ODBC Trace File”.

Check the MyODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in MyODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See Section 1.7.1, “MySQL Mailing Lists”. Please never send the whole MyODBC or ODBC log file!

If you are unable to find out what's wrong, the last option is to create an archive in `tar` or Zip format that contains a MyODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to ftp://ftp.mysql.com/pub/mysql/upload/. Only we at MySQL AB has access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

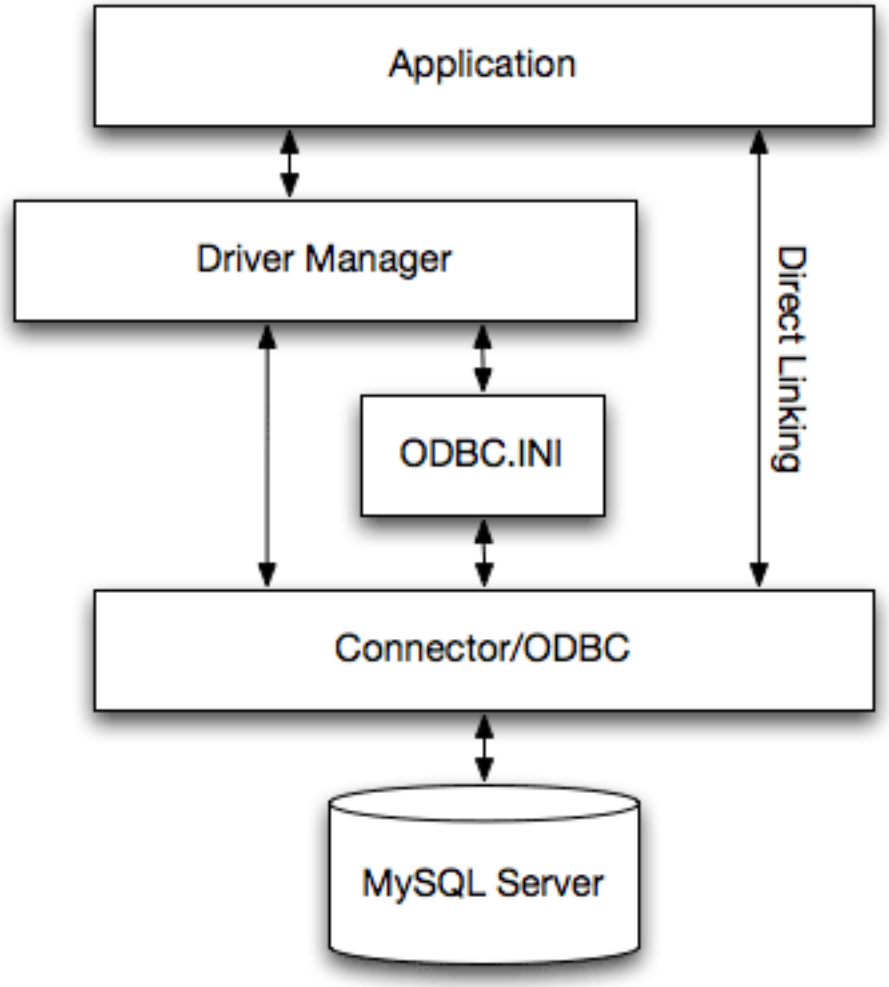
If the program works with some other SQL server, you should include an ODBC log file where you do exactly the same thing in the other SQL server.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

26.1.1.10. How to Submit a MyODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to `<myodbc@lists.mysql.com>`.

26.1.2. General Information About ODBC and MyODBC



26.1.2.1. Introduction to ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by MyODBC is given at Section 26.1.16, “MyODBC API Reference”. For general information about ODBC, see http://www.microsoft.com/data/.

26.1.2.2. MyODBC Architecture

The MyODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

  An application is a program that calls the ODBC API to access the data from the MySQL server. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

  A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

  - Selecting the MySQL server and connecting to it
  - Submitting SQL statements for execution
  - Retrieving results (if any)
  - Processing errors
  - Committing or rolling back the transaction enclosing the SQL statement
  - Disconnecting from the MySQL server

  Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

  The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

  - Resolves Data Source Names (DSN)
  - Driver loading and unloading
  - Processes ODBC function calls or passes them to the driver

- **MyODBC Driver:**

  The MyODBC driver is a library that implements the functions in the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by the MySQL.

- **ODBC.INI:**

  `ODBC.INI` is the ODBC configuration file that stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded using the Data Source Name. The driver uses this to read connection parameters based on the DSN specified. For more information, Section 26.1.9, “MyODBC Configuration”.

- **MySQL Server:**

  The MySQL server is the source of data. MySQL is:

  - A database management system (DBMS)
  - A relational database management system (RDBMS)
  - Open Source Software

26.1.2.3. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN)
- Driver loading and unloading
- Processing ODBC function calls or passing them to the driver

The following driver managers are commonly used:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), http://www.microsoft.com/data/
- unixODBC Driver Manager for Unix (`libodbc.so`), http://www.unixodbc.org.
- iODBC ODBC Driver Manager for Unix (`libiodbc.so`), http://www.iodbc.org

MyODBC 3.51 also is shipped with UnixODBC beginning with version 2.1.2.

26.1.2.4. Types of MySQL ODBC Drivers

MySQL AB supports two Open Source ODBC drivers for accessing MySQL functionality through

the ODBC API: MyODBC (MyODBC 2.50) and MySQL ODBC 3.51 Driver (MyODBC 3.51).

Note: From this section onward, we refer both the drivers generically as MyODBC. Whenever there is a difference, we use the original names.

26.1.3. How to Install MyODBC

MyODBC works on Windows 9x, Me, NT, 2000, XP, and 2003, and on most Unix platforms.

MyODBC is Open Source. You can find the newest version at http://dev.mysql.com/downloads/connector/odbc/. Please note that the 2.50.x versions are LGPL licensed, whereas the 3.51.x versions are GPL licensed.

If you have problem with MyODBC and your program also works with OLEDB, you should try the OLEDB driver.

Normally you need to install MyODBC only on Windows machines. You need MyODBC for Unix only if you have a program like ColdFusion that is running on a Unix machine and uses ODBC to connect for database access.

If you want to install MyODBC on a Unix box, you also need an ODBC manager. MyODBC is known to work with most Unix ODBC managers.

- To make a connection to a Unix box from a Windows box with an ODBC application (one that doesn't support MySQL natively), you must first install MyODBC on the Windows machine.
- The user and Windows machine must have access privileges for the MySQL server on the Unix machine. This is set up with the `GRANT` command. See Section 13.5.1.3, “`GRANT` and `REVOKE` Syntax”.
- You must create an ODBC DSN entry as follows:
  1. Open the Control Panel on the Windows machine.
  2. Double-click the `ODBC Data Sources 32-bit` icon.
  3. Click the tab `User DSN`.
  4. Click the `Add` button.
  5. Select MySQL in the screen `Create New Data Source` and click the `Finish` button.
  6. The MySQL Driver default configuration screen is shown. See Section 26.1.9.2, “Configuring a MyODBC DSN on Windows”.
- Start your application and select the ODBC driver with the DSN that you specified in the ODBC administrator.

Notice that other configuration options are shown on the MySQL screen that you can try if you run into problems (options such as trace, don't prompt on connect, and so forth).

26.1.4. Installing MyODBC from a Binary Distribution on Windows

To install MyODBC on Windows, you should download the appropriate distribution file from http://dev.mysql.com/downloads/connector/odbc/, unpack it, and execute the `MyODBC-`*`VERSION`*`.exe` file.

On Windows, you may get the following error when trying to install the older MyODBC 2.50

driver:

```
An error occurred while copying C:\WINDOWS\SYSTEM\MFC30.DLL. Restart
Windows and try installing again (before running any applications
which use ODBC)
```

The problem is that some other program is using ODBC. Because of how Windows is designed, you may not be able in this case to install new ODBC drivers with Microsoft's ODBC setup program. In most cases, you can continue by pressing `Ignore` to copy the rest of the MyODBC files and the final installation should still work. If it doesn't, the solution is to re-boot your computer in "safe mode." Choose safe mode by pressing F8 just before your machine starts Windows during re-booting, install MyODBC, and re-boot to normal mode.

26.1.5. Installing MyODBC from a Binary Distribution on Unix

26.1.5.1. Installing MyODBC from an RPM Distribution

To install or upgrade MyODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of MyODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh MyODBC-3.51.01.i386-1.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh MyODBC-3.51.01.i386-1.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC` respectively. Proceed onto Section 26.1.9.3, "Configuring a MyODBC DSN on Unix".

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e MyODBC
```

26.1.5.2. Installing MyODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps:

```
shell> su root
shell> gunzip MyODBC-3.51.01-i686-pc-linux.tar.gz
shell> tar xvf MyODBC-3.51.01-i686-pc-linux.tar
shell> cd MyODBC-3.51.01-i686-pc-linux
```

Read the installation instructions in the `INSTALL-BINARY` file and execute these commands.

```
shell> cp libmyodbc* /usr/local/lib
```

```
shell> cp odbc.ini /usr/local/etc
shell> export ODBCINI=/usr/local/etc/odbc.ini
```

Then proceed on to Section 26.1.9.3, “Configuring a MyODBC DSN on Unix”, to configure the DSN for MyODBC. For more information, refer to the `INSTALL-BINARY` file that comes with your distribution.

26.1.6. Installing MyODBC from a Source Distribution on Windows

26.1.6.1. Requirements

- MDAC, Microsoft Data Access SDK from http://www.microsoft.com/data/.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit http://dev.mysql.com/downloads/.

26.1.6.2. Building MyODBC 3.51

MyODBC 3.51 source distributions include `Makefiles` that uses `nmake`. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change location into that folder. The following command assumes the folder is named `myodbc3-src`:

   ```
   C:\> cd myodbc3-src
   ```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

   ```
   C:\> nmake -f Makefile
   C:\> nmake -f Makefile install
   ```

   `nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

   `nmake -f Makefile install` installs (copies) the driver DLLs and libraries(`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

   ```
   C:\> nmake -f Makefile_debug
   C:\> nmake -f Makefile_debug install
   ```

4. You can clean and rebuild the driver by using:

   ```
   C:\> nmake -f Makefile clean
   C:\> nmake -f Makefile install
   ```

Note:

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp.
- If you are using the BitKeeper tree for compiling, All Windows-specific `Makefiles` are named as `Win_Makefile*`.

26.1.6.3. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

26.1.6.4. Building MyODBC 2.50

The MyODBC 2.50 source distribution includes VC workspace files. You can build the driver using these files (`.dsp` and `.dsw`) directly by loading them from Microsoft Visual Studio 6.0 or higher.

26.1.7. Installing MyODBC from a Source Distribution on Unix

26.1.7.1. Requirements

- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit http://dev.mysql.com/downloads/.
- The MySQL library must be configured with the `--enable-thread-safe-client` option. libmysqlclient installed as a shared library.
- One of the following Unix ODBC driver managers must be installed:
  - `iodbc` 3.0 or later (http://www.iodbc.org)
  - `unixodbc` Alpha 3 or later (http://www.unixodbc.org)
- If using a **character set** that isn't compiled into the MySQL client library (the defaults are: latin1 big5 czech euc_kr gb2312 gbk sjis tis620 ujis) then you need to install the mysql character definitions from the `charsets` directory into *`SHAREDIR`* (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine.

Once you have all the required files, unpack the source files to a separate directory and follow the instructions as given below:

26.1.7.2. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure your MyODBC build. Typically you do this using options on the `configure` command line. You can also affect

`configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile MyODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=`*`DIR`* option, where *`DIR`* is the directory where the MySQL is installed.

   MySQL compile options can be determined by running *`DIR`*`/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager(`iodbc` or `unixobc`).

   - If you are using `iodbc` and `iodbc` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=`*`DIR`* option, where *`DIR`* is the directory where iodbc is installed.

     If the iodbc headers do not reside in *`DIR`*`/include`, you can use the `--with-iodbc-includes=`*`INCDIR`* option to specify their location.

     The applies to libraries. If they are not in *`DIR`*`/lib`, you can use the `--with-iodbc-libs=`*`LIBDIR`* option.

   - If you are using `unixODBC`, use the `--with-unixODBC=`*`DIR`* option (case sensitive) to make `configure` look for `unixODBC` instead of `iodbc` by default, *`DIR`* is the directory where unixODBC is installed.

     If the unixODBC headers and libraries aren't located in *`DIR`*`/include` and *`DIR`*`/lib`, use the `--with-unixODBC-includes=`*`INCDIR`* and `--with-unixODBC-libs=`*`LIBDIR`* options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the MyODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \
         --with-iodbc=/usr/local \
         --with-mysql-path=/usr/local/mysql
```

26.1.7.3. Thread-Safe Client

In order to link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled(default) using

```
--disable-thread-safe
```

This option enables the building of driver thread-safe library `libmyodbc3_r.so` from by linking with mysql thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

In case while configuring with thread-safe option, and gotten into a configure error; then look at the `config.log` and see if it is due to the lack of thread-libraries in the system; and supply one with LIBS options i.e.

```
LIBS="-lpthread" ./configure ..
```

26.1.7.4. Shared or Static Options

You can enable or disable the shared and static versions using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

26.1.7.5. Enabling Debugging Information

By default, all the binary distributions are built as non-debugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug`) when you run `configure`.

26.1.7.6. Enabling the Documentation

This option is available only for BK clone trees; not for normal source distributions.

By default, the driver is built with (`--without-docs`); And in case if you want the documentation to be taken care in the normal build, then configure with:

```
--with-docs
```

26.1.7.7. Building and Compilation

To build the driver libraries, you have to just execute `make`, which takes care of everything.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to <myodbc@lists.mysql.com> for further assistance.

26.1.7.8. Building Shared Libraries

On most platforms, MySQL doesn't build or support `.so` (shared) client libraries by default, because building with shared libraries has caused us problems in the past.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd MyODBC-3.51.01
shell> make
```

```
shell> cd driver
shell> CC=/usr/bin/gcc \
     $CC -bundle -flat_namespace -undefined error \
         -o .libs/libmyodbc3-3.51.01.so \
         catalog.o connect.o cursor.o dll.o error.o execute.o \
         handle.o info.o misc.o myodbc3.o options.o prepare.o \
         results.o transact.o utility.o \
         -L/usr/local/mysql/lib/mysql/ \
         -L/usr/local/iodbc/lib/ \
         -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using unixODBC instead of iODBC, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to MyODBC library directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `--prefix`).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
     $CC -bundle -flat_namespace -undefined error
      -o .libs/libmyodbc3_r-3.51.01.so
      catalog.o connect.o cursor.o dll.o error.o execute.o
      handle.o info.o misc.o myodbc3.o options.o prepare.o
      results.o transact.o utility.o
      -L/usr/local/mysql/lib/mysql/
      -L/usr/local/iodbc/lib/
      -lz -lc -lmysqlclient_r -liodbcinst
```

26.1.7.9. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For MyODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe MyODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For MyODBC 2.5.0:

- `libmyodbc.so`
- `libmyodbc-2.50.39.so`, where 2.50.39 is the version of the driver
- `libmyodbc.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

26.1.7.10. Testing MyODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, just execute:

```
shell> make test
```

Make sure the DSN 'myodbc3' is configured first in `odbc.ini` and environment variable `ODBCINI` is pointing to the right `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command line arguments to each sample.

26.1.7.11. Mac OS X Notes

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
           --with-unixODBC=/usr/local
           --with-mysql-path=/usr/local/mysql
           --disable-shared
           --enable-gui=no
           --host=powerpc-apple
```

The command assumes that the unixODBC and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
     $CC -bundle -flat_namespace -undefined error
         -o .libs/libmyodbc3-3.51.01.so *.o
         -L/usr/local/mysql/lib/
         -L/usr/local/iodbc/lib
         -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
     $CC -bundle -flat_namespace -undefined error
     -o .libs/libmyodbc3-3.51.01.so *.o
     -L/usr/local/mysql/lib/
     -L/usr/local/iodbc/lib
     -liodbcinst -lmysqlclienti_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using unixODBC instead of iODBC and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

26.1.7.12. HP-UX Notes

To build the driver on HP-UX 10.x or 11.x, make use of the following `configure` example:

If using `cc`:

```
shell> CC="cc" \
     CFLAGS="+z" \
     LDFLAGS="-Wl,+b:-Wl,+s" \
     ./configure --prefix=/usr/local
           --with-unixodbc=/usr/local
           --with-mysql-path=/usr/local/mysql/lib/mysql
           --enable-shared
           --enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
     LDFLAGS="-Wl,+b:-Wl,+s" \
     ./configure --prefix=/usr/local
           --with-unixodbc=/usr/local
           --with-mysql-path=/usr/local/mysql
           --enable-shared
           --enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to see whether or not you need to have the MySQL client libraries path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

26.1.7.13. AIX Notes:

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
           --with-unixodbc=/usr/local
           --with-mysql-path=/usr/local/mysql
           --disable-shared
           --enable-thread-safe
```

NOTE: For more information about how to build and set up the static and shared libraries across the different platforms refer to ' Using static and shared libraries across platforms [http://www.fortran-2000.com/ArnaudRecipes/sharedlib.html]'.

26.1.8. Installing MyODBC from the BitKeeper Development Source Tree

Note: You should read this section only if you are interested in helping us test our new code.

To obtain our most recent development source tree, use these instructions:

1. See Section 2.8.3, “Installing from the Development Source Tree”, for instructions on how to download and install BitKeeper.

2. After BitKeeper is installed, first go to the directory you want to work from, and then use this command if you want to clone the MyODBC 3.51 branch:

   ```
   shell> bk clone bk://mysql.bkbits.net/myodbc3 myodbc-3.51
   ```

   In the preceding example, the source tree is set up in the `myodbc-3.51/` or by default `myodbc3/` subdirectory of your current directory. If you are behind the firewall and can only initiate HTTP connections, you can also use BitKeeper via HTTP. If you are required to use a proxy server, simply set the environment variable `http_proxy` to point to your proxy:

   ```
   shell> export http_proxy="http://your.proxy.server:8080/"
   ```

   Replace the `bk://` with `http://` when doing a clone. Example:

   ```
   shell> bk clone http://mysql.bkbits.net/myodbc3 myodbc-3.51
   ```

   The initial download of the source tree may take a while, depending on the speed of your connection; be patient.

3. You need GNU `autoconf` 2.52 (or newer), `automake` 1.4, `libtool` 1.4, and `m4` to run the next set of commands.

   ```
   shell> cd myodbc-3.51
   shell> bk -r edit
   shell> aclocal; autoheader; autoconf;  automake;
   shell> ./configure  # Add your favorite options here
   shell> make
   ```

   For more information on how to build, refer to `INSTALL` file located in the same directory. On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver, for more information, see Section 26.1.6, “Installing MyODBC from a Source Distribution on Windows”.

4. When the build is done, run `make install` to install the MyODBC 3.51 driver on your system.

5. If you have gotten to the `make` stage and the distribution does not compile, please report it to <myodbc@lists.mysql.com>.

6. After the initial `bk clone` operation to get the source tree, you should run `bk pull` periodically to get the updates.

7. You can examine the change history for the tree with all the diffs by using `bk sccstool`. If you see some funny diffs or code that you have a question about, do not hesitate to send email message to <myodbc@lists.mysql.com>.

   Also, if you think you have a better idea on how to do something, send an email message to the same address with a patch. `bk diffs` produces a patch for you after you have made changes to the source. If you do not have the time to code your idea, just send a description.

8. BitKeeper has a help utility that you can access via `bk helptool`.

You can also browse changesets, comments and source code online by browsing to http://mysql.bkbits.net:8080/myodbc3.

26.1.9. MyODBC Configuration

This section describes how to configure MyODBC, including DSN creation and the different arguments that the driver takes as an input arguments in the connection string. It also describes how to create an ODBC trace file.

26.1.9.1. What is a Data Source Name?

A "data source" is a place where data comes from. The data source must have a persistent identifier, the Data Source Name. Using the Data Source Name, MySQL can access initialization information. With the initialization information, MySQL knows where to access the database and what settings to use when the access starts.

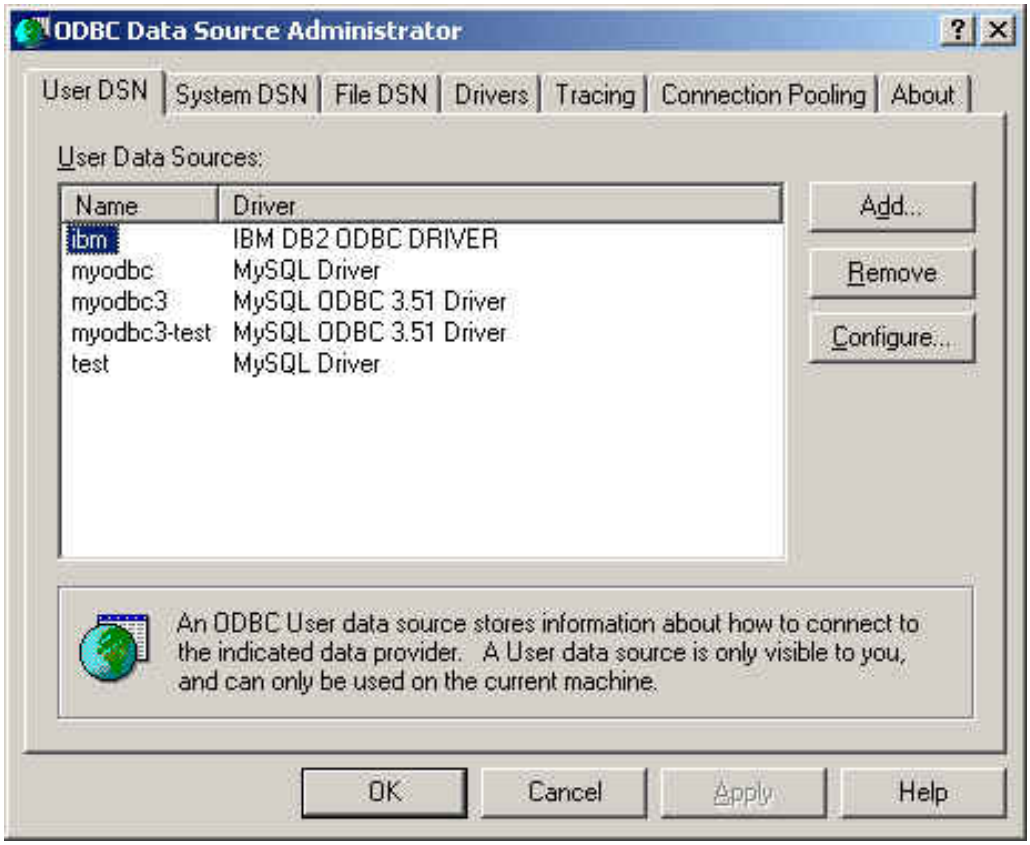
In effect, the data source is the *path* to the data. In different contexts this might mean different things, but typically it identifies a running MySQL server (for example via a network address or service name), plus the default database for that server at connection time, plus necessary connection information such as the port. The MySQL drivers (and, on Windows systems, the ODBC Driver Manager) use the data source for connecting. An administrative utility called the Microsoft ODBC Data Source Administrator may be useful for this purpose.

There are two places where the initialization information might be: in the Windows registry (on a Windows system), or in a DSN file (on any system).

If the information is in the Windows registry, it is called a "Machine data source". It might be a "User data source", in which case only one user can see it. Or it might be a "System data source" in which case it is accessible to all users on the computer, or indeed to all users connected to the computer, if the users are connected by Microsoft Windows NT services. When you run the ODBC Data Administration program, you have a choice whether to use "User" or "System" -- there are separate tabs.

If the information is in a DSN file, it is called a "File data source". This is a text file. Its advantages are: (a) it is an option for any kind of computer, not just a computer with a Windows operating system; (b) its contents can be transmitted or copied relatively easily.

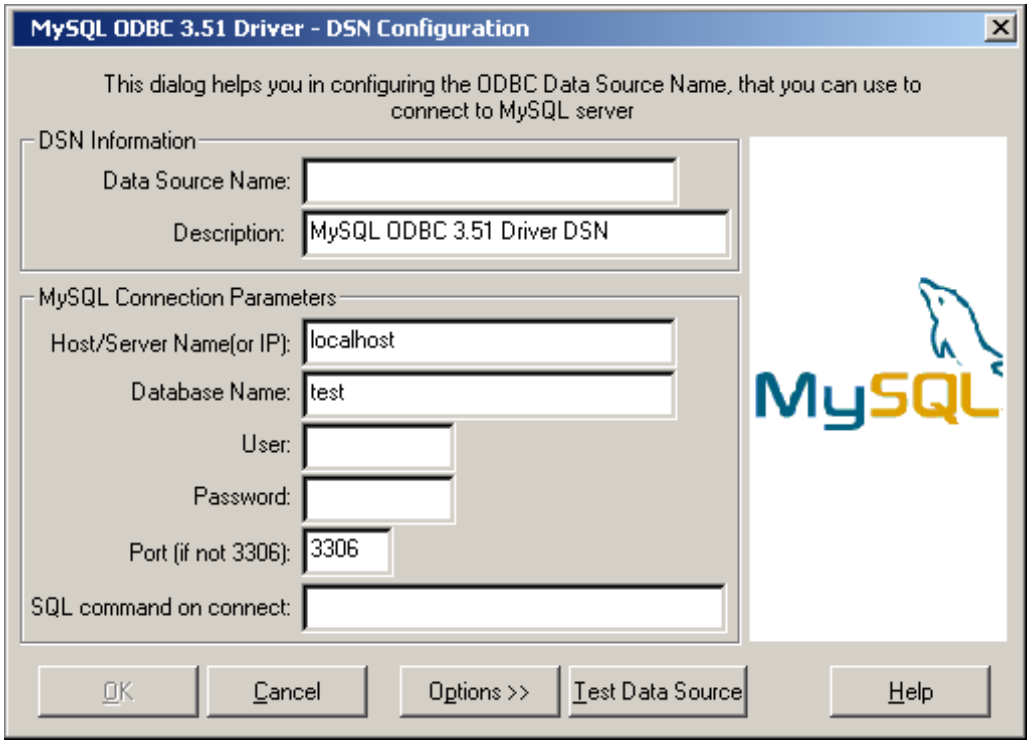
26.1.9.2. Configuring a MyODBC DSN on Windows



To add and configure a new MyODBC data source on Windows, use the `ODBC Data Source Administrator`. The `ODBC Administrator` updates your data source connection information. As you add data sources, the `ODBC Administrator` updates the registry information for you.

To open the `ODBC Administrator` from the Control Panel:

1. Click `Start`, point to `Settings`, and then click `Control Panel`.
2. On computers running Microsoft Windows 2000 or newer, double-click `Administrative Tools`, and then double-click `Data Sources (ODBC)`. On computers running older versions of Windows, double-click `32-bit ODBC` or `ODBC`.



The `ODBC Data Source Administrator` dialog box appears, as shown here:

Click `Help` for detailed information about each tab of the `ODBC Data Source Administrator` dialog box.

To add a data source on Windows:

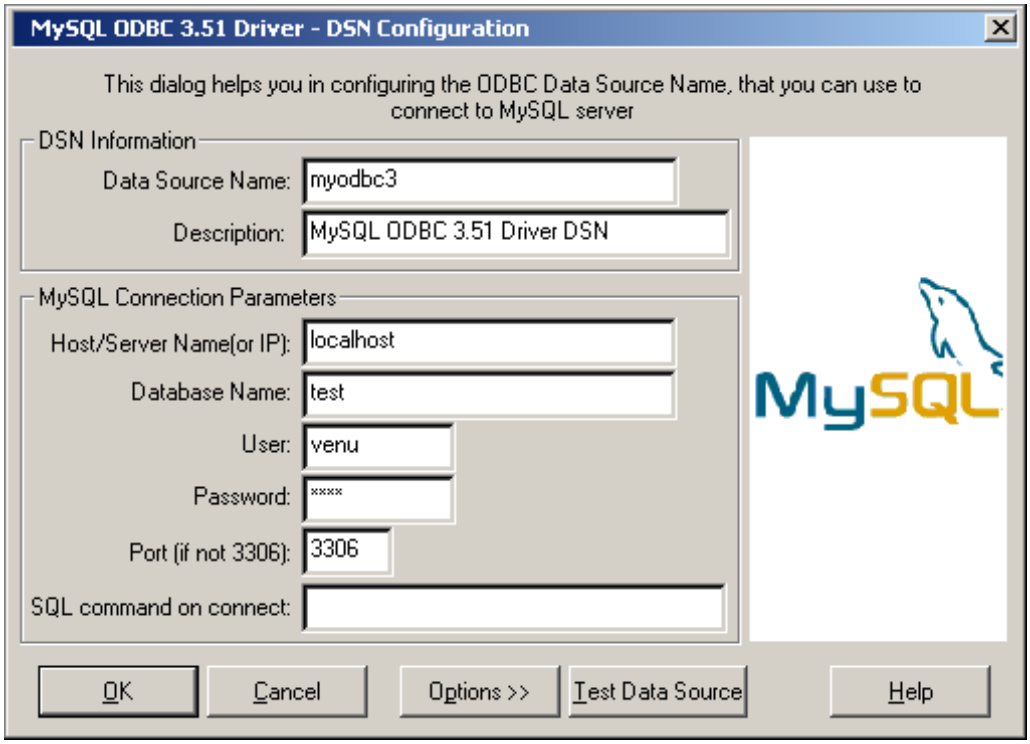
1. Open the `ODBC Data Source Administrator`.
2. In the `ODBC Data Source Administrator` dialog box, click `Add`. The `Create New Data Source` dialog box appears.
3. Select `MySQL ODBC 3.51 Driver`, and then click `Finish`. The `MySQL ODBC 3.51 Driver - DSN Configuration` dialog box appears, as shown here:

4. In the `Data Source Name` box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the `Description` box, enter the description needed for the DSN.

6. For `Host or Server Name (or IP)` box, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.

7. In the `Database Name` box, enter the name of the MySQL database that you want to use as the default database.



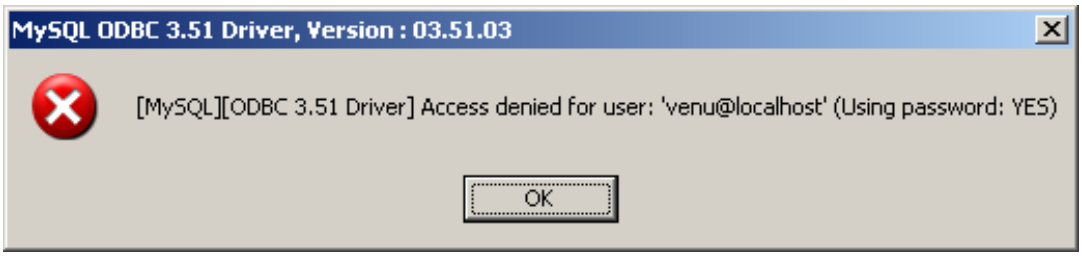
8. In the `User` box, enter your MySQL username (your database user ID).

9. In the `Password` box, enter your password.

10. In the `Port` box, enter the port number if it is not the default (3306).

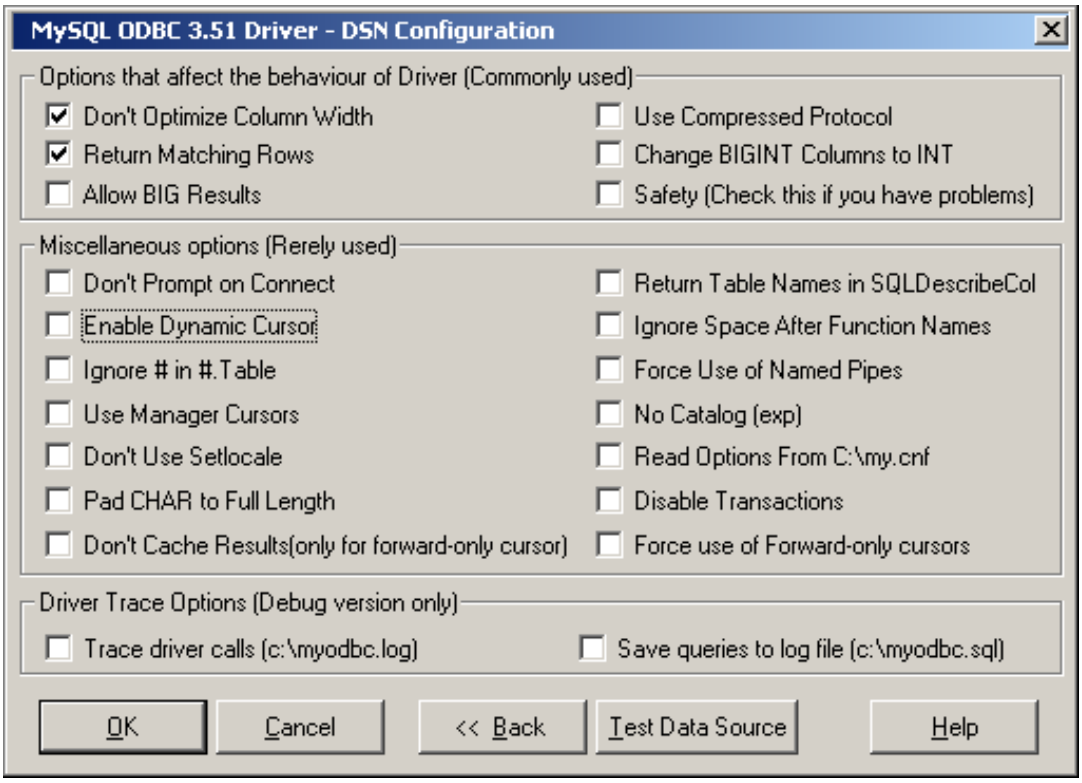
11. In the `SQL Command` box, you can enter an optional SQL statement that you want to issue automatically after the connection has been established.

    The final dialog looks like this:



Click `OK` to add this data source.

Note: Upon clicking `OK`, the `Data Sources` dialog box appears, and the `ODBC Administrator` updates the registry information. The username and connect string that you entered become the default connection values for this data source when you connect to it.



You can also test whether your settings are suitable for connecting to the server using the button `Test Data Source`. This feature is available only for the MyODBC 3.51 driver. A successful test results in the following window:

A failed test results in an error:

The DSN configuration dialog also has an `Options` button. If you select it, the following options dialog appears displaying that control driver behavior. Refer to Section 26.1.9.4, “Connection Parameters”, for information about the meaning of these options.

Note: The options listed under `Driver Trace Options` are disabled (grayed out) unless you are using the debugging version of the driver DLL.

To modify a data source on Windows:

1. Open the `ODBC Data Source Administrator`. Click the appropriate DSN tab.
2. Select the MySQL data source that you want to modify and then click `Configure`. The `MySQL ODBC 3.51 Driver - DSN Configuration` dialog box appears.
3. Modify the applicable data source fields, and then click `OK`.

When you have finished modifying the information in this dialog box, the `ODBC Administrator` updates the registry information.

26.1.9.3. Configuring a MyODBC DSN on Unix

On `Unix`, you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc` and `myodbc3` as the DSN names for MyODBC 2.50 and MyODBC 3.51, respectively:

```
;
;  odbc.ini configuration for MyODBC and MyODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc      = MyODBC 2.50 Driver DSN
myodbc3     = MyODBC 3.51 Driver DSN

[myodbc]
Driver       = /usr/local/lib/libmyodbc.so
Description  = MyODBC 2.50 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
```

```
Password     =
Database     = test
OPTION       = 3
SOCKET       =

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = MyODBC 3.51 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = MyODBC 3.51 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =
```

Refer to the Section 26.1.9.4, “Connection Parameters”, for the list of connection parameters that can be supplied.

Note: If you are using unixODBC, you can use the following tools in order to set up the DSN:

- ODBCConfig GUI tool(HOWTO: ODBCConfig [http://www.unixodbc.org/config.html])
- odbcinst

In some cases when using unixODBC, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

26.1.9.4. Connection Parameters

You can specify the following parameters for MyODBC in the `[Data Source Name]` section of an `ODBC.INI` file or through the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
`user`	ODBC (on Windows)	The username used to connect to MySQL.
`server`	`localhost`	The hostname of the MySQL server.
`database`		The default database.
`option`	0	Options that specify how MyODBC should work. See below.

port	3306	The TCP/IP port to use if server is not localhost.
stmt		A statement to execute when connecting to MySQL.
password		The password for the user account on server.
socket		The Unix socket file or Windows named pipe to connect to if server is localhost.

The option argument is used to tell MyODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the option argument. The following options are listed in the order in which they appear in the MyODBC connect screen:

Value	Description
1	The client can't handle that MyODBC returns the real width of a column.
2	The client can't handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns “found rows” instead. You must have MySQL 3.21.14 or newer to get this to work.
4	Make a debug log in c:\myodbc.log. This is the same as putting MYSQL_DEBUG=d:t:O,c::\myodbc.log in AUTOEXEC.BAT. (On Unix, the file is /tmp/myodbc.log.)
8	Don't set any packet limit for results and parameters.
16	Don't prompt for questions even if driver would like to prompt.
32	Enable or disable the dynamic cursor support. (Not allowed in MyODBC 2.50.)
64	Ignore use of database name in db_name.tbl_name.col_name.
128	Force use of ODBC manager cursors (experimental).
256	Disable the use of extended fetch (experimental).
512	Pad CHAR columns to full column length.
1024	SQLDescribeCol() returns fully qualified column names.
2048	Use the compressed client/server protocol.
4096	Tell server to ignore space after function name and before ‘(’ (needed by PowerBuilder). This makes all function names keywords.
8192	Connect with named pipes to a mysqld server running on NT.
16384	Change LONGLONG columns to INT columns (some applications can't handle LONGLONG).
32768	Return 'user' as Table_qualifier and Table_owner from SQLTables (experimental).
65536	Read parameters from the [client] and [odbc] groups from my.cnf.
131072	Add some extra safety checks (should not be needed but...).
262144	Disable transactions.
524288	Enable query logging to c:\myodbc.sql(/tmp/myodbc.sql) file. (Enabled only in debug mode.)
1048576	Do not cache the results locally in the driver, instead read from server (mysql_use_result()). This works only for forward-only cursors. This option is very important in dealing with large tables when you don't want the driver to cache the entire result set.
2097152	Force the use of Forward-only cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use non-cache result sets, then this option ensures the forward-only cursor behavior.

To select multiple options, add together their values. For example, setting option to 12 (4+8) gives you debugging without packet limits.

The default `myodbc3.dll` is compiled for optimal performance. If you want to debug MyODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in MyODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

For MyODBC 2.50, `myodbc.dll` and `myodbcd.dll` are used instead.

The following table shows some recommended `option` values for various configurations:

Configuration	Option Value
Microsoft Access	3
Microsoft Visual Basic	3
Large tables with too many rows	2049
Driver trace generation (Debug mode)	4
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

26.1.9.5. Connecting Without a Predefined DSN

Yes. You can connect to the MySQL server using SQLDriverConnect, by specifying the `DRIVER` name field. Here are the connection strings for MyODBC using DSN-Less connection:

For MyODBC 2.50:

```
ConnectionString = "DRIVER={MySQL};\
                   SERVER=localhost;\
                   DATABASE=test;\
                   USER=venu;\
                   PASSWORD=venu;\
                   OPTION=3;"
```

For MyODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
                   SERVER=localhost;\
                   DATABASE=test;\
                   USER=venu;\
                   PASSWORD=venu;\
                   OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
                   "SERVER=localhost;"
                   "DATABASE=test;"
                   "USER=venu;"
                   "PASSWORD=venu;"
                   "OPTION=3;"
```

Refer to the Section 26.1.9.4, “Connection Parameters”, for the list of connection parameters that can be supplied.

26.1.9.6. Establishing a Remote Connection to System A from System B

If you want to connect to system A from system B with a username and password of `myuser` and `mypassword`, here is a simple procedure.

On system A, follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a username of `myuser` that can connect from system B using a password of `myuser`:

   ```
   GRANT ALL ON *.* to 'myuser'@'B' IDENTIFIED BY 'mypassword';
   ```

3. The `GRANT` statement grants all privileges to user `myuser` for connecting from system B using the password `mypassword`. To execute this statement, you should be either `root` on system A (or another user who has appropriate privileges). For more information about MySQL privileges, refer to Section 5.8, “MySQL User Account Management”.

On system B, follow these steps:

1. Configure a MyODBC DSN using the following connection parameters:

   ```
   DSN             = remote_test
   SERVER or HOST = A (or IP address of system A)
   DATABASE        = test (The default database or an appropriate one)
   USER            = myuser
   PASSWORD        = mypassword
   ```

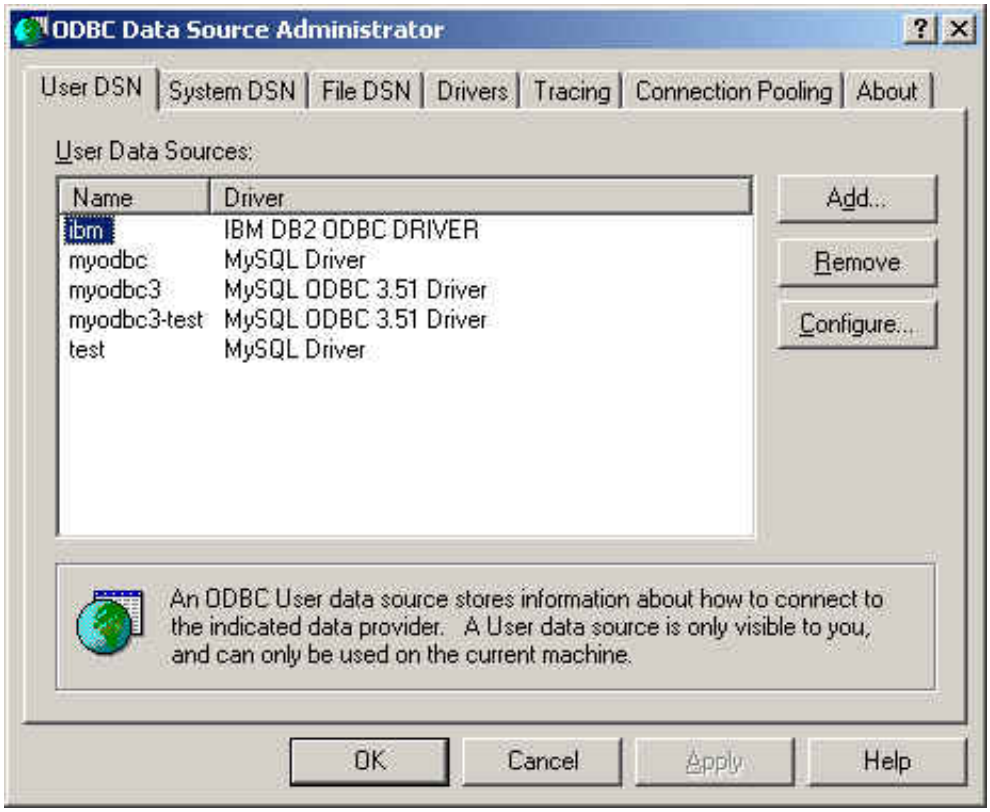
   To set up a DSN-less connection, refer to Section 26.1.9.5, “Connecting Without a Predefined DSN”.

2. Check whether you are able to access system A from system B by using ping or other means. If you are not able to reach system A, check your network or Internet connections or contact your system administrator.
3. Try to connect using `DSN=remote_test`. If it fails, trace the MyODBC log, and take the further steps based on the error message from the log. If you need further assistance, send a detailed mail message to <myodbc@lists.mysql.com>.

You can also find a simple HOWTO at http://www.phphelp.com/tutorial/using-myodbc-to-connect-to-a-remote-database.html.

26.1.9.7. Getting an ODBC Trace File

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the `ODBC Manager` (the log you get when requesting logs from `ODBC ADMIN`) and MyODBC.



To get an ODBC trace through Driver Manager, do the following:

- Open ODBC Data source administrator:
  1. Click `Start`, point to `Settings`, and then click `Control Panel`.
  2. On computers running Microsoft Windows 2000, XP, or 2003, double-click `Administrative Tools`, and then double-click `Data Sources (ODBC)`, as shown below.

On computers running an earlier version of Microsoft Windows, double-click `32-bit ODBC` or `ODBC` in the Control Panel.

3. The `ODBC Data Source Administrator` dialog box appears, as shown below:

4. Click Help for detailed information about each tab of the ODBC Data Source Administrator dialog box.

- Enable the trace option. The procedure for this differs for Windows and Unix.

  To enable the trace option on Windows:

  1. The `Tracing` tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.

  2. When you activate tracing from the `Tracing` tab, the `Driver Manager` logs all ODBC function calls for all subsequently run applications.

  3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.

  4. Tracing ceases only after you click `Stop Tracing Now`. Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

To enable the trace option on Unix:

1. On Unix, you need to explicitly set the `Trace` option in the `ODBC.INI` file.

   Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

   ```
   TraceFile  = /tmp/odbc.trace
   Trace      = 1
   ```

   `TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at HOWTO-ODBCConfig [http://www.unixodbc.org/config.html].

To generate a MyODBC log, do the following:

1. Ensure that you are using the driver debug DLL (that is, `myodbc3d.dll` and not `myodbc3.dll` for MyODBC 3.51, and `myodbcd.dll` for MyODBC 2.50).

   The easiest way to do this is to get `myodbc3d.dll` (or `myodbcd.dll`) from the MyODBC 3.51 distribution and copy it over the `myodbc3.dll` (or `myodbc.dll`), which is probably in your `C:\windows\system32` or `C:\winnt\system32` directory. Note that you probably want to restore the old `myodbc.dll` file when you have finished testing, as this is a lot faster than `myodbc3d.dll` (or `myodbcd.dll`), so do keep a backup copy of original DLLs.

2. Enable the `Trace MyODBC` option flag in the MyODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbcd.dll` driver (see above). On Linux or if you are using DSN-Less connection, then you need to supply `OPTION=4` in the connection string.

3. Start your application and try to get it to fail. Then check the MyODBC trace file to find out what could be wrong.

   If you find out something is wrong, please send a mail message to <myodbc@lists.mysql.com> (or to <support@mysql.com> if you have a support contract from MySQL AB) with a brief description of the problem, with the following additional information:

   - MyODBC version
   - ODBC Driver Manager type and version
   - MySQL server version
   - ODBC trace from Driver Manager
   - MyODBC log file from MyODBC driver
   - Simple reproducible sample

   Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

   Also, before posting the bug, check the MyODBC mailing list archive at http://lists.mysql.com/.

26.1.9.8. Applications Tested with MyODBC

MyODBC has been tested with the following applications:

- MS Access 95, 97, 2000, and 2002
- C++-Builder, Borland Builder 4
- Centura Team Developer (formerly Gupta SQL/Windows)
- ColdFusion (on Solaris and NT with service pack 5), How-to: MySQL and Coldfusion [http://www.njwtech.net/addons/coldfusion/mysql.html]. Troubleshooting Data Sources and Database Connectivity for UnixPlatforms [http://www.macromedia.com/v1/handlers/index.cfm?ID=11328&Method=Full&PageCall=/support/index.cfm].
- Crystal Reports
- DataJunction
- Delphi
- ERwin
- MS Excel
- iHTML
- FileMaker Pro
- FoxPro
- Notes 4.5/4.6
- MS Visio Enterprise 2000

- Vision
- Visual Objects
- Visual Interdev
- SBSS
- Perl DBD-ODBC
- Paradox
- Powerbuilder
- Powerdesigner 32-bit
- MS Visual C++
- Visual Basic
- ODBC.NET through CSharp(C#), VB and C++
- Data Architect(http://thekompany.com/products/dataarchitect/)
- SQLExpress for Xbase++(http://www.SQLExpress.net)
- Open Office (http://www.openoffice.org) How-to: MySQL + OpenOffice [http://dba.openoffice.org/proposals/MySQL_OOo.html]. How-to: OpenOffice + MyODBC + unixODBC [http://www.unixodbc.org/doc/OOoMySQL.pdf].
- Star Office (http://wwws.sun.com/software/star/staroffice/6.0/index.html)
- G2-ODBC bridge (http://www.gensym.com)
- Sambar Server (http://www.sambarserver.info) How-to: MyODBC + SambarServer + MySQL [http://www.sambarserver.info/article.php?sid=66].

If you know of any other applications that work with MyODBC, please send mail to `<myodbc@lists.mysql.com>` about them.

26.1.9.9. Programs Known to Work With MyODBC

Most programs should work with MyODBC, but for each of those listed here, we have tested it ourselves or received confirmation from some user that it works. Many of the descriptions provide workarounds for problems that you might encounter.

- **Program**

  Comment

- Access

  To make Access work:

  - If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (`Microsoft Data Access Components`) from http://www.microsoft.com/data/. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

    You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be

found at http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114. This fixes some cases where columns are marked as `#DELETED#` in Access.

Note: If you are using MySQL 3.22, you must to apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the MyODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration. That is, use `TIMESTAMP`, not `TIMESTAMP(`*n*`)`, *n* < 14.
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

  Old records still display as `#DELETED#`, but newly added/updated records are displayed properly.
- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

  Don't use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.
- In some cases, Access may generate illegal SQL statements that MySQL can't understand. You can fix this by selecting `"Query|SQLSpecific|Pass-Through"` from the Access menu.
- On NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access can't always handle `DATE` columns properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.

- ADO

  When you are coding with the ADO API and MyODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of -1 for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

- Active server pages (ASP)

  You should select the `Return matching rows` option.

- BDE applications

  To get these to work, you should select the `Don't optimize column widths` and `Return matching rows` options.

- Borland Builder 4

  When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

- ColdFusion (On Unix)

  The following information is taken from the ColdFusion documentation:

  Use the following information to configure ColdFusion Server for Linux to use the unixODBC driver with MyODBC for MySQL data sources. Allaire has verified that MyODBC 2.50.26 works with MySQL 3.22.27 and ColdFusion for Linux. (Any newer version should also work.) You can download MyODBC at http://dev.mysql.com/downloads/connector/odbc/.

  ColdFusion version 4.5.1 allows you to us the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC datasources drop-down list, you must build and copy the MyODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

  The Contrib directory contains the program `mydsn-xxx.zip` which allows you to build and remove the DSN registry file for the MyODBC driver on Coldfusion applications.

- DataJunction

  You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

- Excel

  Works. A few tips:

  - If you have problems with dates, try to select them as strings using the `CONCAT()` function. For example:

```
SELECT CONCAT(rise_time), CONCAT(set_time)
  FROM sunrise_sunset;
```

Values retrieved as strings this way should be correctly recognized as time values by Excel97.

The purpose of `CONCAT()` in this example is to fool ODBC into thinking the column is of "string type." Without the `CONCAT()`, ODBC knows the column is of time type, and Excel does not understand that.

Note that this is a bug in Excel, because it automatically converts a string to a time. This would be great if the source was a text file, but is unfortunate when the source is an ODBC connection that reports exact types for each column.

- Word

  To retrieve data from MySQL to Word/Excel documents, you need to use the MyODBC driver and the Add-in Microsoft Query help.

  For example, create a database with a table containing two columns of text:

  - Insert rows using the `mysql` client command-line tool.
  - Create a DSN file using the ODBC manager, for example, `my` for the database that was just created.
  - Open the Word application.
  - Create a blank new document.
  - In the `Database` tool bar, press the `Insert Database` button.
  - Press the `Get Data` button.
  - At the right hand of the `Get Data` screen, press the `Ms Query` button.
  - In `Ms Query`, create a new data source using the `my` DSN file.
  - Select the new query.
  - Select the columns that you want.
  - Make a filter if you want.
  - Make a Sort if you want.
  - Select `Return Data to Microsoft Word`.
  - Click `Finish`.
  - Click `Insert Data` and select the records.
  - Click `OK` and you see the rows in your Word document.

- odbcadmin

  Test program for ODBC.

- Delphi

  You must use BDE 3.2 or newer. Select the `Don't optimize column width` option when connecting to MySQL.

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for MyODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab','MySQL',Memo1.Lines);
```

- C++ Builder

  Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, though this has not been a problem.

- Vision

  You should select the `Return matching rows` option.

- Visual Basic

  To be able to update a table, you must define a primary key for the table.

  Visual Basic with ADO can't handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the MyODBC connect screen. You may also want to select the `Return matching rows` option.

- VisualInterDev

  If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter` Try selecting the `Change BIGINT columns to INT` option in the MyODBC connect screen.

- Visual Objects

You should select the `Don't optimize column widths` option.

- MS Visio Enterprise 2000

  We made database model diagram by connecting from MS Vision Enterprise 2000 to MySQL via MyODBC (2.50.37 or greater) and using Visio's reverse engineer function to retrieve information about the DB (Visio shows all the column definitions, primary keys, Indexes and so on). Also we tested by designing new tables in Visio and exported them to MySQL via MyODBC.

26.1.10. MyODBC Connection-Related Issues

This section answers MyODBC connection-related questions.

26.1.10.1. While Configuring a MyODBC DSN, a `Could Not Load Translator or Setup Library` Error Occurs

For more information, refer to MS KnowledgeBase Article(Q260558) [http://support.microsoft.com/default.aspx?scid=kb;EN-US;q260558]. Also, make sure you have the latest valid `ctl3d32.dll` in your system directory.

26.1.10.2. While Connecting, an `Access denied` Error Occurs

Refer to Section 5.7.8, “Causes of `Access denied` Errors”.

26.1.10.3. INFO: About ODBC Connection Pooling

Refer to this document about connection pooling: http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470.

26.1.11. MyODBC and Microsoft Access

This section of the document answers questions related to MyODBC with Microsoft Access.

26.1.11.1. How to Set Up Microsoft Access to Work with MySQL using MyODBC?

The following must be done on your client PC in order to make Microsoft Access work with MyODBC.

1. If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (`Microsoft Data Access Components`) from http://www.microsoft.com/data/. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

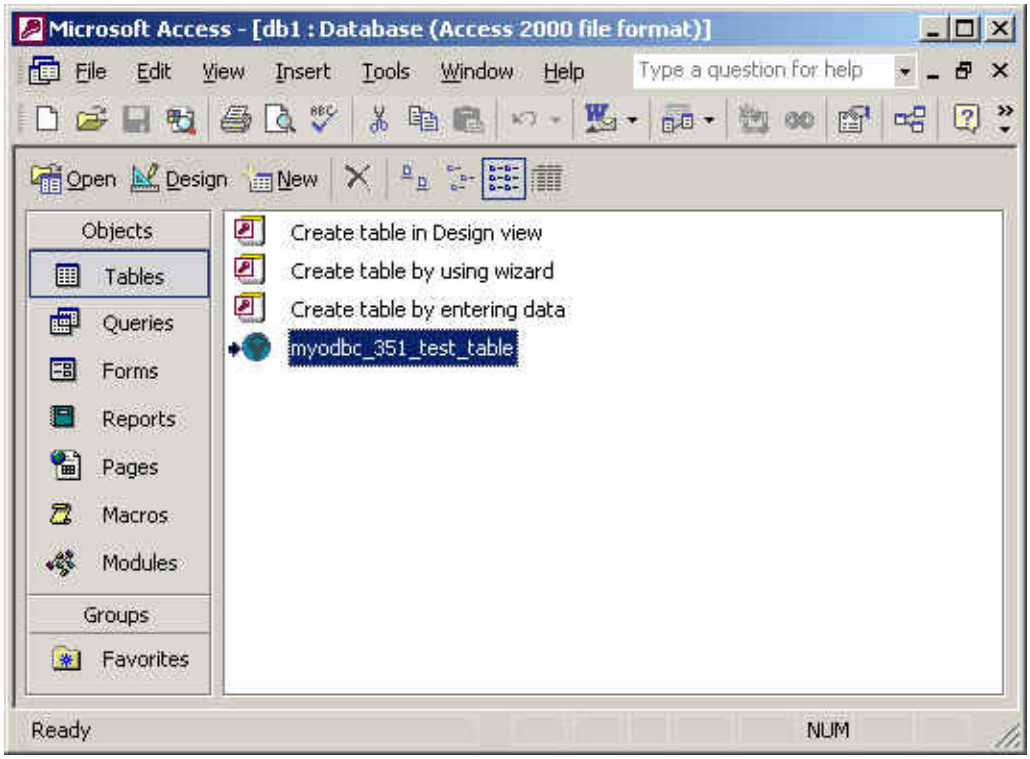
   You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114. This fixes some cases where columns are marked as `#DELETED#` in Access.

   Note: If you are using MySQL 3.22, you must to apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

2. Install the latest version of MySQL from http://dev.mysql.com/downloads/.

3. Install the latest version of MyODBC 3.51 or 2.50 from http://dev.mysql.com/downloads/connector/odbc/.

4. For all Access versions, you should enable the `Return matching rows` option.



5. Start working with Access as the front end for MySQL Server through MyODBC.

26.1.11.2. How to Export a Table or Query from Access to MySQL?

You cannot export a table or query to MySQL unless you have installed MyODBC.

To export a table from Access to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the `table` or `query` you want to export, and then in the `File` menu, select `Export`.

3. In the `Export Object Type` *`Object name`* `To` dialog box, in the `Save As Type` box, select `ODBC Databases ()` as shown here:

4. In the `Export` dialog box, enter a name for the file (or use the suggested name), and then select `OK`.

5. The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the MyODBC or MyODBC 3.51 data source that you want to export to. To define a new data source for MyODBC, please Section 26.1.9.2, “Configuring a MyODBC DSN on Windows”.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

26.1.11.3. How to Import or Link MySQL Database Tables to Access?

You cannot export a table or query to MySQL database unless you have installed the MyODBC.

To import or link a table or tables from MySQL to Access, follow the instructions:

1. Open a database, or switch to the Database window for the open database.

2. To import tables, on the `File` menu, point to `Get External Data`, and then click `Import`. To link tables, on the File menu, point to `Get External Data`, and then click `Link Tables`.

3. In the `Import` (or `Link`) dialog box, in the Files Of Type box, select `ODBC Databases()`. The Select Data Source dialog box lists the defined data sources The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the MyODBC or MyODBC 3.51 data source that you want to export to. To define a new data source for the MyODBC or MyODBC 3.51 driver, please Section 26.1.9.2, “Configuring a MyODBC DSN on Windows”.

4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click `OK`.

5. Microsoft Access connects to the MySQL server through `ODBC data source` and displays the list of tables that you can `import` or `link`.

6. Click each table that you want to `import` or `link`, and then click `OK`. If you're linking a table and it doesn't have an index that uniquely identifies each record, Microsoft Access displays a list of the fields in the linked table. Click a field or a combination of fields that uniquely identifies each record, and then click `OK`.

26.1.11.4. The Structure or Location of a Linked Table has been Changed. Can I See Those Changes Locally in Linked Tables?

Yes. Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

To view or refresh links:

1. Open the database that contains links to tables.

2. On the `Tools` menu, point to `Add-ins` (`Database Utilities` in Access 2000 or newer), and then click `Linked Table Manager`.

3. Select the check box for the tables whose links you want to refresh.

4. Click OK to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the `Select New Location of` <table name> dialog box in which you can specify its the table's new location.If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

To change the path for a set of linked tables:

1. Open the database that contains links to tables.
2. On the `Tools` menu, point to `Add-ins` (`Database Utilities` in Access 2000 or newer), and then click `Linked Table Manager`.
3. Select the `Always Prompt For A New Location` check box.
4. Select the check box for the tables whose links you want to change, and then click `OK`.
5. In the `Select New Location of` <table name> dialog box, specify the new location, click `Open`, and then click `OK`.

26.1.11.5. When I Insert or Update a Record in Linked Tables, I Get #DELETED#

If the inserted or updated records are shown as `#DELETED#` in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (`Microsoft Data Access Components`) from http://www.microsoft.com/data/. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

  You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114. This fixes some cases where columns are marked as `#DELETED#` in Access.

  Note: If you are using MySQL 3.22, you must to apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the MyODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration. That is, use `TIMESTAMP`, not `TIMESTAMP(`*n*`)`, *n* < 14.
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

26.1.11.6. How Do I Handle Write Conflicts or Row Location Errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.
```

```
Row cannot be located for updating. Some values may have been changed since it was last read.
```

26.1.11.7. Whenever I Export a Table from Access 97, a Strange Syntax Error Occurs

This is a strange issue from Access 97, and doesn't appear with Access 2000 or 2002. You can overcome this by upgrading the MyODBC driver to at least MyODBC 3.51.02.

26.1.11.8. Access Returns `Another user has modified the record that you have modified` While Editing Records

With some programs, this error may occur: `Another user has modified the record that you have modified`. In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double float fields. Some programs may fail when they compare single floats.

If these strategies don't help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a MyODBC log to help you figure out why things go wrong. For instructions, see Section 26.1.9.7, “Getting an ODBC Trace File”.

26.1.11.9. How to Trap ODBC Login Error Messages in Access?

Read “How to Trap ODBC Login Error Messages in Access” at http://support.microsoft.com/support/kb/articles/Q124/9/01.asp?LN=EN-US&SD=gn&FR=0%3CP%3E.

26.1.11.10. How Do I Optimize Access for Performance with MyODBC?

- Optimizing for Client/Server Performance [http://support.microsoft.com/default.aspx?scid=kb;en-us;128808]
- Tips for Converting Applications to Using ODBCDirect [http://support.microsoft.com/default.aspx?scid=kb;en-us;164481]
- Tips for Optimizing Queries on Attached SQL Tables [http://support.microsoft.com/default.aspx?scid=kb;EN-US;q99321]

26.1.11.11. I Have Very Long Tables. What is the Best Configuration for MyODBC to Access These Tables?

If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:

- Return Matching Rows (2)
- Allow BIG Results (8).

These add up to a value of 10 (`OPTION=10`).

26.1.11.12. How to Set the QueryTimeout Value for ODBC Connections?

Read “Set the QueryTimeout Value for ODBC Connections” at http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756.

26.1.11.13. INFO: Tools to Export/Import from/to Access to/from MySQL

Refer to converters [http://www.mysql.com/portal/software/convertors/] section for list of available tools.

26.1.12. MyODBC and Microsoft VBA and ASP

This section answers questions related to using MyODBC with Microsoft Visual Basic(ADO, DAO & RDO) and ASP.

26.1.12.1. Why Does `SELECT COUNT(*) FROM tbl_name` Return an Error?

It's because the `COUNT(*)` expression is returning a `BIGINT`, and ADO can't make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

26.1.12.2. Whenever I Use the `AppendChunk()` or `GetChunk()` ADO Methods, I Get an Error `Multiple-step operation generated errors. Check each status value.`

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the cursor location is specified as adUseServer. On the other hand, you can overcome this error by using adUseClient.

A simple example can be found from, http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm

26.1.12.3. How to Find the Total Number of Rows Affected by a Particular SQL Statement in ADO?

You can make use of `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnnexecute.asp.

26.1.12.4. How Do I Handle Blob Data in Visual Basic?

Here is an excellent article from Mike Hillyer (<m.hillyer@telusplanet.net>); explaining how to insert or fetch data from blob columns through MyODBC from ADO: MySQL BLOB columns and Visual Basic 6 [http://www.dynamergy.com/mike/articles/blobaccessvb.html].

26.1.12.5. How Do I Map Visual Basic Data Types to MySQL Types?

Here is yet another good article from Mike Hillyer (<m.hillyer@telusplanet.net>): How to map Visual basic data type to MySQL types [http://www.dynamergy.com/mike/articles/vbmysqldatatypes.php].

26.1.12.6. SAMPLES: VB with ADO, DAO and RDO

A simple examples for the usage of ADO, DAO and RDO with VB can be found here:

- ADO sample: Section 26.1.19, “MyODBC With VB: ADO, DAO and RDO”
- DAO sample: Section 26.1.19, “MyODBC With VB: ADO, DAO and RDO”
- RDO sample: Section 26.1.19, “MyODBC With VB: ADO, DAO and RDO”

If you find any other good example or HOW-TO on ADO/DAO/RDO, please send the details to <myodbc@lists.mysql.com>

26.1.12.7. ASP and MySQL with MyODBC

For more information about how to access MySQL via ASP using MyODBC, refer to the following articles:

- Using MyODBC To Access Your MySQL Database Via ASP [http://www.devarticles.com/c/a/ASP/Using-MyODBC-To-Access-Your-MySQL-Database-Via-ASP/]
- ASP and MySQL at DWAM.NT [http://www.dwam.net/mysql/asp_myodbc.asp]

A Frequently Asked Questions list for ASP can be found at http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp.

26.1.12.8. INFO: Frequently Asked Questions on ActiveX Data Objects (ADO)

For information, see ActiveX Data Objects(ADO) Frequently Asked Questions [http://support.microsoft.com/default.aspx?scid=kb;EN-US;q183606].

26.1.13. MyODBC and Third-Party ODBC Tools

This section answers questions related to MyODBC with various ODBC-related tools; such as Microsoft Word, Excel and ColdFusion.

26.1.13.1. How to Retrieve Data from MySQL into MS-Word/Excel Documents?

To retrieve data from MySQL to Word/Excel documents, you need to use the MyODBC driver and the Add-in Microsoft Query help.

For example, create a database with a table containing two columns of text:

- Insert rows using the `mysql` client command-line tool.
- Create a DSN file using the ODBC manager, for example, `my` for the database that was just created.
- Open the Word application.
- Create a blank new document.
- In the `Database` tool bar, press the `Insert Database` button.
- Press the `Get Data` button.
- At the right hand of the `Get Data` screen, press the `Ms Query` button.
- In `Ms Query`, create a new data source using the `my` DSN file.
- Select the new query.
- Select the columns that you want.
- Make a filter if you want.
- Make a Sort if you want.
- Select `Return Data to Microsoft Word`.
- Click `Finish`.
- Click `Insert Data` and select the records.
- Click `OK` and you see the rows in your Word document.

26.1.13.2. Exporting Tables from MS DTS to MySQL Using MyODBC Results in a Syntax Error

This is an issue similar to that of Access 97 when your table consists of `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your MyODBC driver to version 3.51.02 or higher.

26.1.13.3. HOWTO: Configure MySQL+MyODBC+unixODBC+ColdFusion on Solaris

Refer to MySQL ColdFusion unixODBC MyODBC and Solaris - how to succeed [http://dbforums.com/showthread.php?threadid=174934]

26.1.14. MyODBC General Functionality

This section of the document answers questions related to MyODBC general functionality.

26.1.14.1. How to Get the Value of an `AUTO_INCREMENT` Column in ODBC

A common problem is how to get the value of an automatically generated ID from an `INSERT` statement. With ODBC, you can do something like this (assuming that `auto` is an `AUTO_INCREMENT` field):

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

Or, if you are just going to insert the ID into another table, you can do this:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

See Section 25.2.13.3, “How to Get the Unique ID for the Last Inserted Row”.

For the benefit of some ODBC applications (at least Delphi and Access), the following query can be used to find a newly inserted row:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

26.1.14.2. Does MyODBC Support Dynamic Cursor Type?

Yes. MyODBC 3.51 supports `Dynamic cursor` type along with `Forward-only` and `static`.

Due to the performance issues, the driver does not support this feature by default. You can enable this by specifying the connection option flag as `OPTION=32` or by checking the `Enable Dynamic Cursor` option from the DSN configuration.

26.1.14.3. What Causes `Transactions are not enabled` Errors?

The driver returns this error when an application issues any transactional call but the underlying MySQL server either does not support transactions or they are not enabled.

To avoid this problem, you must use a server that has either or both of the `InnoDB` or `BDB` storage engines enabled, and use tables of those types. MySQL servers from version 4.0 and up support `InnoDB` by default. MySQL-Max servers also support `BDB` on platforms where `BDB` is available.

Also, if your server supports transactional storage engines (`InnoDB` and `BDB`) make sure the `disable transactions` option is not set from the DSN configuration.

26.1.14.4. What Causes `Cursor not found` Errors?

This occurs because the application is using old MyODBC 2.50 version, and it did not set the cursor name explicitly through SQLSetCursorName. The fix is to upgrade to MyODBC 3.51 version.

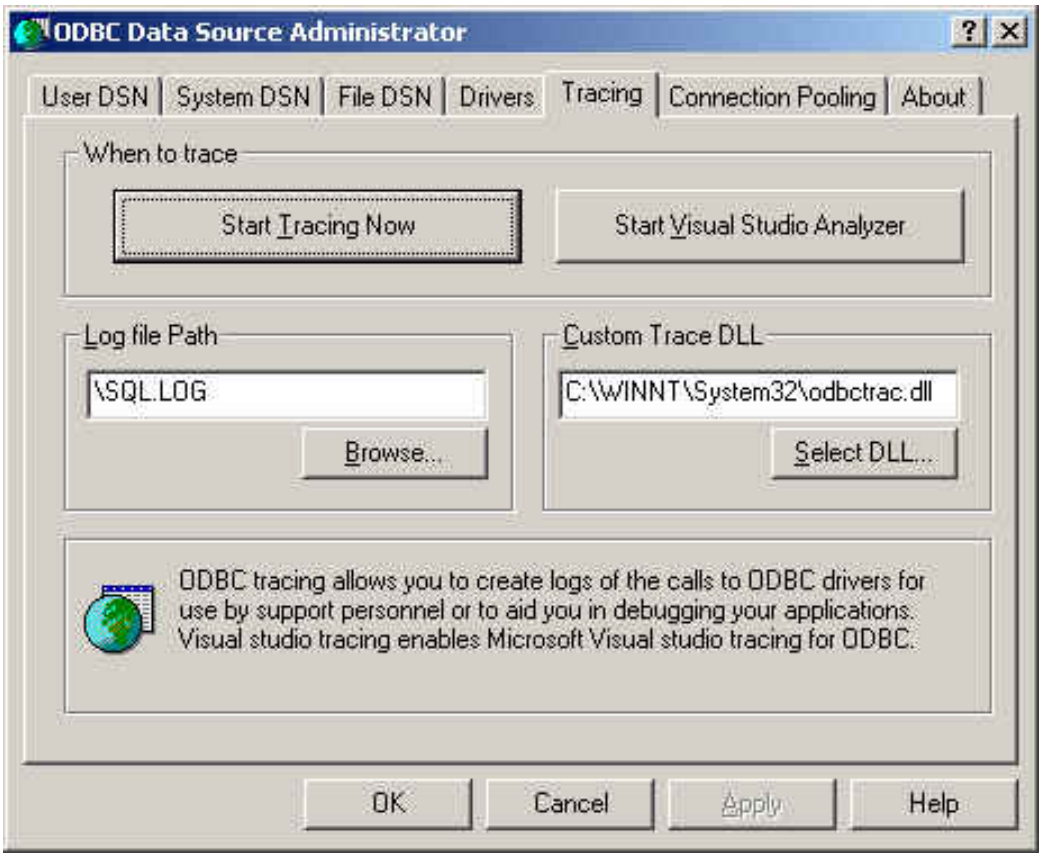
26.1.14.5. Can I Use MyODBC 2.50 Applications with MyODBC 3.51?

Yes. If you find something is not working with MyODBC 3.51 that works with MyODBC 2.50, then send a mail message to `<myodbc@lists.mysql.com>`

26.1.14.6. Can I Access MySQL from .NET Environment Using MyODBC?

Yes. You can make use of **odbc.net** to connect to MySQL through MyODBC. Here are the few basic samples to connect to MySQL from VC.NET and VB.NET.

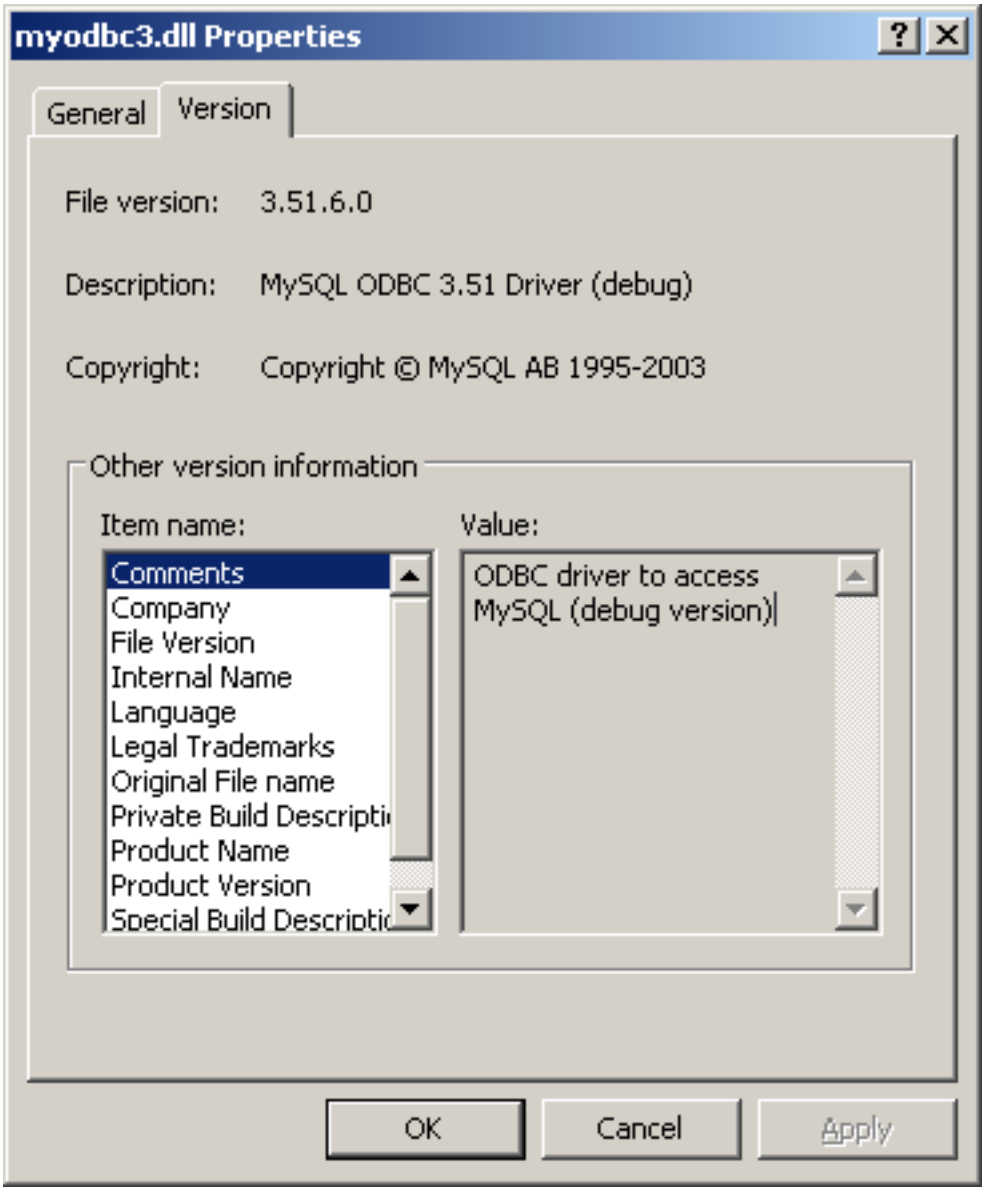
- See Section 26.1.20.1, “ODBC.NET: CSHARP(C#)”.
- See Section 26.1.20.2, “ODBC.NET: VB”.



Here is yet another excellent article "Exploring MySQL on .NET environment [http://www.mysql.com/newsletter/2002-07/a0000000035.html]" by **Venu** (MyODBC developer) that covers about all MySQL .NET interfaces along with some useful examples.

Caution: Using ODBC.NET with MyODBC, while fetching empty string (0 length), it starts giving the SQL_NO_DATA exception. You can get the patch for this from http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243.

26.1.14.7. Why Does MyODBC Perform Poorly, and Also Make a Lot of Disk Activity for Relatively Small Queries?



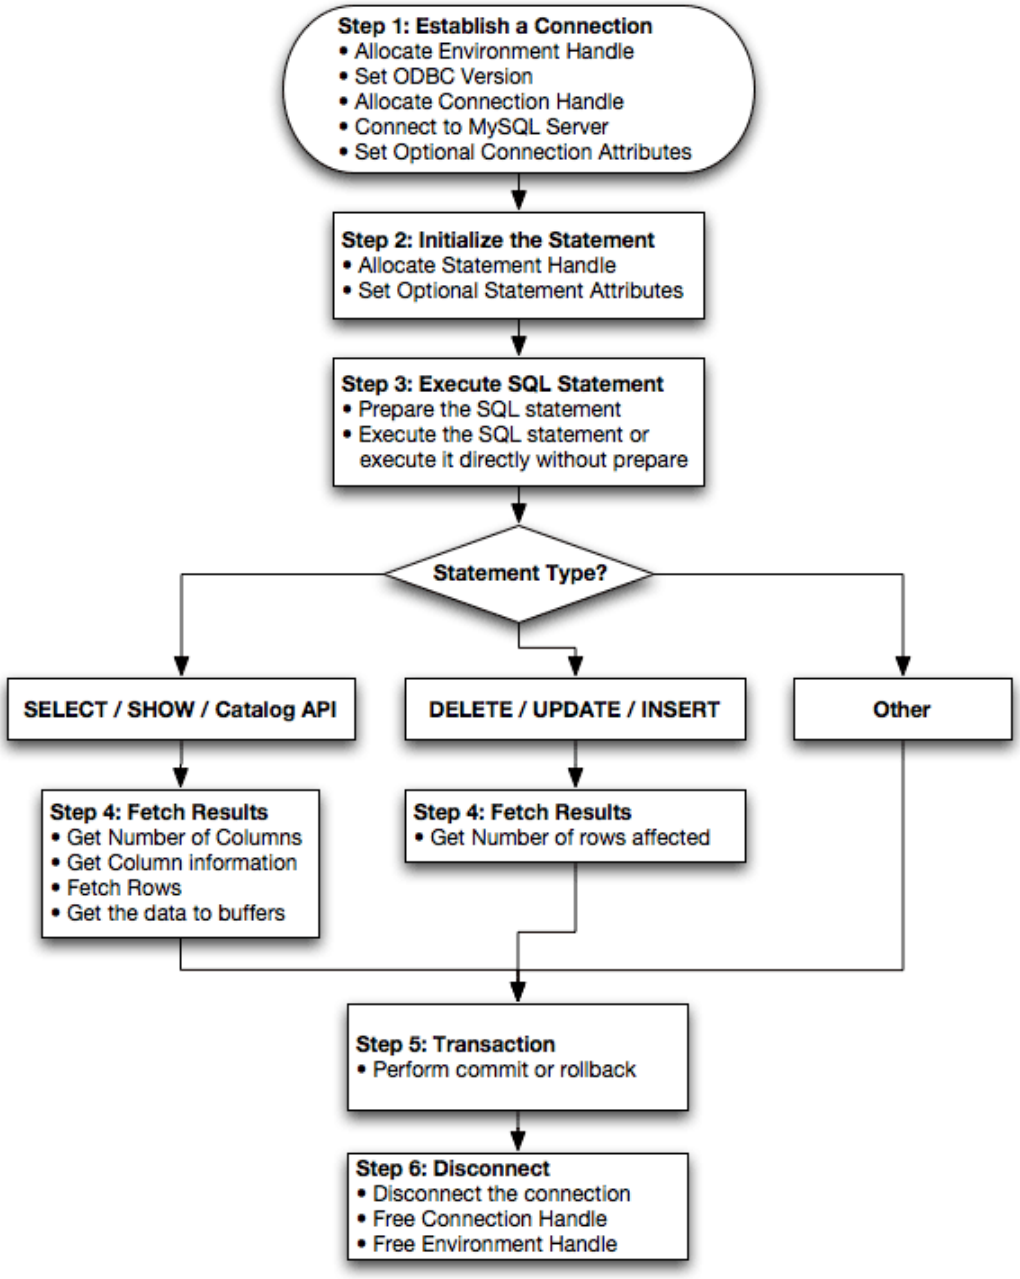
MyODBC is a lot faster than any other ODBC driver. Slowness might be due to not using the following options.

- The **ODBC Tracing** option is turned on. You can cross-check whether this option is not turned on by following the instructions from here [http://support.microsoft.com/default.aspx?scid=kb;EN-US;268591].

  As shown in the above image, the 'When to trace' option from the ODBC Data Source Administrator 'Tracing' tab should always point to 'Start Tracing Now', instead of 'Stop Tracing Now'.

- The **Debug version** of the driver is used. If you are using the debug version of the driver DLL, it can also relatively slow down the query processing time. You can cross-check whether you are using the debug or release version of the DLL from the 'Comments' section of the driver DLL properties (from the system directory, right click on the driver DLL and click on properties) as shown below:

- The **Driver trace and query logs** are enabled. Even if you intent to use the debug version of the driver (you should always use the release version in the production environment), make sure the driver trace and query log options(OPTION=4,524288 respectively) are not enabled as shown below:



26.1.15. Basic MyODBC Application Steps

Interacting with a MySQL server from MyODBC applications involves the following operations:

- Configure the MyODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

26.1.16. MyODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programer's Reference at http://msdn.microsoft.com/library/en-us/odbc/htm/odbcabout_this_manual.asp.

An application can call `SQLGetInfo` function to obtain conformance information about MyODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

Note: For backward compatibility, the MyODBC 3.51 driver supports all deprecated functions.

The following tables list MyODBC API calls grouped by task:

Connecting to a data source:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLAllocHandle	No	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
SQLConnect	Yes	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
SQLDriverConnect	Yes	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
SQLAllocEnv	Yes	Yes	Deprecated	Obtains an environment handle allocated from driver.
SQLAllocConnect	Yes	Yes	Deprecated	Obtains a connection handle

Obtaining information about a driver and data source:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLDataSources	No	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
SQLDrivers	No	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
SQLGetInfo	Yes	Yes	ISO 92	Returns information about a specific driver and data source.
SQLGetFunctions	Yes	Yes	ISO 92	Returns supported driver functions.
SQLGetTypeInfo	Yes	Yes	ISO 92	Returns information about supported data types.

Setting and retrieving driver attributes:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLSetConnectAttr	No	Yes	ISO 92	Sets a connection attribute.
SQLGetConnectAttr	No	Yes	ISO 92	Returns the value of a connection attribute.
SQLSetConnectOption	Yes	Yes	Deprecated	Sets a connection option
SQLGetConnectOption	Yes	Yes	Deprecated	Returns the value of a connection option
SQLSetEnvAttr	No	Yes	ISO 92	Sets an environment attribute.
SQLGetEnvAttr	No	Yes	ISO 92	Returns the value of an environment attribute.
SQLSetStmtAttr	No	Yes	ISO 92	Sets a statement attribute.

SQLGetStmtAttr	No	Yes	ISO 92	Returns the value of a statement attribute.
SQLSetStmtOption	Yes	Yes	Deprecated	Sets a statement option
SQLGetStmtOption	Yes	Yes	Deprecated	Returns the value of a statement option

Preparing SQL requests:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLAllocStmt	Yes	Yes	Deprecated	Allocates a statement handle
SQLPrepare	Yes	Yes	ISO 92	Prepares an SQL statement for later execution.
SQLBindParameter	Yes	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
SQLGetCursorName	Yes	Yes	ISO 92	Returns the cursor name associated with a statement handle.
SQLSetCursorName	Yes	Yes	ISO 92	Specifies a cursor name.
SQLSetScrollOptions	Yes	Yes	ODBC	Sets options that control cursor behavior.

Submitting requests:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLExecute	Yes	Yes	ISO 92	Executes a prepared statement.
SQLExecDirect	Yes	Yes	ISO 92	Executes a statement
SQLNativeSql	Yes	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
SQLDescribeParam	Yes	Yes	ODBC	Returns the description for a specific parameter in a statement.
SQLNumParams	Yes	Yes	ISO 92	Returns the number of parameters in a statement.
SQLParamData	Yes	Yes	ISO 92	Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.)
SQLPutData	Yes	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)

Retrieving results and information about results:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLRowCount	Yes	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResult-	Yes	Yes	ISO 92	Returns the number of columns in

Cols				the result set.
SQLDescribeCol	Yes	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	No	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	No	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	Yes	ODBC	Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	No	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

Retrieving error or diagnostic information:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLError	Yes	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

Obtaining information about the data source's system tables (catalog functions) item:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLColumnPrivileges	Yes	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are auto-

				matically updated when any value in the row is updated by a transaction.
SQLStatistics	Yes	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
SQLTablePrivileges	Yes	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
SQLTables	Yes	Yes	X/Open	Returns the list of table names stored in a specific data source.

Performing transactions:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLTransact	Yes	Yes	Deprecated	Commits or rolls back a transaction
SQLEndTran	No	Yes	ISO 92	Commits or rolls back a transaction.

Terminating a statement:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLFreeStmt	Yes	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
SQLCloseCursor	Yes	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
SQLCancel	Yes	Yes	ISO 92	Cancels an SQL statement.

Terminating a connection:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	**3.51**		
SQLDisconnect	Yes	Yes	ISO 92	Closes the connection.
SQLFreeHandle	No	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
SQLFreeConnect	Yes	Yes	Deprecated	Releases connection handle
SQLFreeEnv	Yes	Yes	Deprecated	Releases an environment handle

26.1.17. MyODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types:

Native Value	SQL Type	C Type

bit	SQL_BIT	SQL_C_BIT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
bigint	SQL_BIGINT	SQL_C_SBIGINT
bigint unsigned	SQL_BIGINT	SQL_C_UBIGINT
long varbinary	SQL_LONGVARBINARY	SQL_C_BINARY
blob	SQL_LONGVARBINARY	SQL_C_BINARY
longblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
mediumblob	SQL_LONGVARBINARY	SQL_C_BINARY
long varchar	SQL_LONGVARCHAR	SQL_C_CHAR
text	SQL_LONGVARCHAR	SQL_C_CHAR
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
char	SQL_CHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
decimal	SQL_DECIMAL	SQL_C_CHAR
integer	SQL_INTEGER	SQL_C_SLONG
integer unsigned	SQL_INTEGER	SQL_C_ULONG
int	SQL_INTEGER	SQL_C_SLONG
int unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
smallint	SQL_SMALLINT	SQL_C_SSHORT
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
real	SQL_FLOAT	SQL_C_DOUBLE
double	SQL_FLOAT	SQL_C_DOUBLE
float	SQL_REAL	SQL_C_FLOAT
double precision	SQL_DOUBLE	SQL_C_DOUBLE
date	SQL_DATE	SQL_C_DATE
time	SQL_TIME	SQL_C_TIME
year	SQL_SMALLINT	SQL_C_SHORT
datetime	SQL_TIMESTAMP	SQL_C_TIMESTAMP
timestamp	SQL_TIMESTAMP	SQL_C_TIMESTAMP
text	SQL_VARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
enum	SQL_VARCHAR	SQL_C_CHAR
set	SQL_VARCHAR	SQL_C_CHAR
bit	SQL_CHAR	SQL_C_CHAR
bool	SQL_CHAR	SQL_C_CHAR

26.1.18. MyODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message

500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	`SQLBindParameter` not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found

0	08S01	08S01	Communication link failure

26.1.19. MyODBC With VB: ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

26.1.19.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using MySQL ODBC 3.51 Driver
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
                      & "SERVER=localhost;"_
                      & " DATABASE=test;"_
                      & "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)
                                & "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
  Debug.Print rs.RecordCount
  rs.MoveFirst
  Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
  For Each fld In rs.Fields
    Debug.Print fld.Name,
    Next
    Debug.Print

    Do Until rs.EOF
    For Each fld In rs.Fields
    Debug.Print fld.Value,
    Next
    rs.MoveNext
    Debug.Print
  Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
```

```
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
  Debug.Print rs.RecordCount
  rs.MoveFirst
  Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
  For Each fld In rs.Fields
    Debug.Print fld.Name,
    Next
    Debug.Print

    Do Until rs.EOF
    For Each fld In rs.Fields
    Debug.Print fld.Value,
    Next
    rs.MoveNext
    Debug.Print
  Loop
rs.Close
conn.Close
End Sub
```

26.1.19.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```
Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
                      & "SERVER=localhost;"_
                      & " DATABASE=test;"_
                      & "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
```

```
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREME
                                                              & "Ts TIMESTAMP(14) NO
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

  For i = 10 To 15
  rs.AddNew
  rs!Name = "insert record" & i
  rs!Id2 = i
  rs.Update
  Next i
           rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub
```

26.1.19.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```
Dim rs As rdoResultset
  Dim cn As New rdoConnection
  Dim cl As rdoColumn
  Dim SQL As String

  'cn.Connect = "DSN=test;"
```

```
  cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
                       & "SERVER=localhost;"_
                       & " DATABASE=test;"_
                       & "UID=venu;PWD=venu; OPTION=3"

  cn.CursorDriver = rdUseOdbc
  cn.EstablishConnection rdDriverPrompt

  'drop table my_rdo
  SQL = "drop table if exists my_rdo"
  cn.Execute SQL, rdExecDirect

  'create table my_rdo
  SQL = "create table my_rdo(id int, name varchar(20))"
  cn.Execute SQL, rdExecDirect

  'insert - direct
  SQL = "insert into my_rdo values (100,'venu')"
  cn.Execute SQL, rdExecDirect

  SQL = "insert into my_rdo values (200,'MySQL')"
  cn.Execute SQL, rdExecDirect

  'rs insert
  SQL = "select * from my_rdo"
  Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
  rs.AddNew
  rs!id = 300
  rs!Name = "Insert1"
  rs.Update
  rs.Close

  'rs insert
  SQL = "select * from my_rdo"
  Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
  rs.AddNew
  rs!id = 400
  rs!Name = "Insert 2"
  rs.Update
  rs.Close

  'rs update
  SQL = "select * from my_rdo"
  Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
  rs.Edit
  rs!id = 999
  rs!Name = "updated"
  rs.Update
  rs.Close

  'fetch back...
  SQL = "select * from my_rdo"
  Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
  Do Until rs.EOF
  For Each cl In rs.rdoColumns
              Debug.Print cl.Value,
    Next
    rs.MoveNext
    Debug.Print
            Loop
  Debug.Print "Row count="; rs.RowCount

  'close
  rs.Close
  cn.Close

End Sub
```

26.1.20. MyODBC with Microsoft .NET

This section contains simple examples that demonstrate the use of MyODBC drivers with ODBC.NET.

26.1.20.1. ODBC.NET: CSHARP(C#)

The following sample creates a table `my_odbc_net` and demonstrates the use in C#.

```
/**
* @sample    : mycon.cs
* @purpose   : Demo sample for ODBC.NET using MyODBC
* @author    : Venu, <venu@mysql.com>
*
* (C) Copyright MySQL AB, 1995-2004
*
**/

/* build command
*
*  csc /t:exe
*      /out:mycon.exe mycon.cs
*      /r:Microsoft.Data.Odbc.dll
*/

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
class mycon
{
  static void Main(string[] args)
  {
    try
    {
      //Connection string for MyODBC 2.50
      /*string MyConString = "DRIVER={MySQL};" +
                           "SERVER=localhost;" +
                           "DATABASE=test;" +
                           "UID=venu;" +
                           "PASSWORD=venu;" +
                           "OPTION=3";
      */
      //Connection string for MyODBC 3.51
      string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                           "SERVER=localhost;" +
                           "DATABASE=test;" +
                           "UID=venu;" +
                           "PASSWORD=venu;" +

26.2. MySQL Connector/NET

26.2.1. Introduction

MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#.

MySQL Connector/NET includes full support for:

- MySQL 5.0 features (such as stored procedures)
- MySQL 4.1 features (server-side prepared statements, Unicode, and shared memory access, and so forth)
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.

- Protocol compression which allows for compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

The developers of MySQL Connector/NET greatly value the input of our users in the software development process. If you find MySQL Connector/NET lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

Additional resources

- Community support for MySQL Connector/NET can be found through the forums at http://forums.mysql.com.
- Community support for MySQL Connector/NET can also be found through the mailing lists at http://lists.mysql.com.
- Paid support is available from MySQL AB. Additional information is available at http://www.mysql.com/support/.

This document is intended as a user's guide to MySQL Connector/NET and not as a syntax reference. If you need detailed syntax information you should read the `Documentation.chm` file included with the MySQL Connector/NET distribution.

26.2.2. Downloading and Installing MySQL Connector/NET

MySQL Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework developed by Novell (see http://www.mono-project.com).

MySQL Connector/NET is installed through the use of a Windows Installer (`.msi`) installation package, which can be used to install MySQL Connector/NET on all Windows operating systems. The MSI package in contained within a ZIP archive named `mysql-connector-net-`*`version`*`.zip`, where *`version`* indicates the MySQL Connector/NET version.

MySQL Connector/NET is available for download from http://dev.mysql.com/downloads/connector/net/1.0.html.

The Windows Installer engine was updated with the release of Windows XP; those using an older version can reference this Microsoft Knowledge Base article [http://support.microsoft.com/default.aspx?scid=kb;EN-US;292539] for information on upgrading to the latest version.

To install MySQL Connector/NET, right-click on the MSI file and select Install. The installation will begin automatically after the installer prompts you for your installation preferences. The `Typical` installation is recommended for most users.

If you are having problems running the installer, you can download a ZIP file without an installer as an alternative. That file is called `mysql-connector-net-`*`version`*`-noinstall.zip`. Us-

ing a ZIP program, unpack it to a directory of your choice.

Unless you choose otherwise, MySQL Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of MySQL Connector/NET you are installing. New installations do not overwrite existing versions of MySQL Connector/NET.

26.2.3. Connector/NET Architecture

MySQL Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of MySQL Connector/NET:

- `MySqlCommand`: Represents an SQL statement to execute against a MySQL database.
- `MySqlCommandBuilder`: Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- `MySqlConnection`: Represents an open connection to a MySQL Server database.
- `MySqlDataAdapter`: Represents a set of data commands and a database connection that are used to fill a dataset and update a MySQL database.
- `MySqlDataReader`: Provides a means of reading a forward-only stream of rows from a MySQL database.
- `MySqlException`: The exception that is thrown when MySQL returns an error.
- `MySqlHelper`: Helper class that makes it easier to work with the provider.
- `MySqlTransaction`: Represents an SQL transaction to be made in a MySQL database.

Each of these objects will be described in the upcoming sections. These sections are intended to be an overview of the major classes of MySQL Connector/NET, and not a syntax reference. If you need more detailed information you should read the `Documentation.chm` file included with the MySQL Connector/NET distribution.

26.2.3.1. The MySqlCommand Class

The `MySqlCommand` class represents an SQL statement to execute against a MySQL database.

Note: Prior versions of the provider used the '@' symbol to mark parameters in SQL. This is incompatible with MySQL user variables, so the provider now uses the '?' symbol to locate parameters in SQL. To support older code, you can set 'old syntax=yes' in your connection string. If you do this, please be aware that an exception will not be thrown if you fail to define a parameter that you intended to use in your SQL.

26.2.3.1.1. Properties

The following properties are available:

- `CommandText`: Gets or sets the SQL statement to execute at the data source.
- `CommandTimeout`: Gets or sets the wait time before terminating the attempt to execute a command and generating an error.
- `CommandType`: Gets or sets a value indicating how the CommandText property is to be interpreted. Possible types are `StoredProcedure`, `TableDirect`, and `Text`.
- `Connection`: Gets or sets the MySqlConnection used by this instance of the MySqlCommand.

- `IsPrepared`: Is true if this command has been prepared, false otherwise.
- `Parameters`: Gets the MySqlParameterCollection.
- `Transaction`: Gets or sets the MySqlTransaction within which the MySqlCommand executes.
- `UpdatedRowSource`: Gets or sets how command results are applied to the DataRow when used by the Update method of the DbDataAdapter.

26.2.3.1.2. Methods

The following methods are available:

- `Cancel`: Attempts to cancel the execution of a MySqlCommand. *This operation is not supported.*
- `Clone`: Creates a clone of this MySqlCommand object. CommandText, Connection, and Transaction properties are included as well as the entire parameter list.
- `CreateParameter`: Creates a new instance of a MySqlParameter object.
- `Dispose`: Disposes of this instance of MySqlCommand.
- `ExecuteNonQuery`: Executes an SQL statement against the connection and returns the number of rows affected.
- `ExecuteReader`: Sends the CommandText to the Connection and builds a MySqlDataReader.
- `ExecuteScalar`: Executes the query, and returns the first column of the first row in the result set returned by the query. Extra columns or rows are ignored.
- `Prepare`: Creates a prepared version of the command on an instance of MySQL Server.

26.2.3.1.3. Usage

The following example creates a MySqlCommand and a MySqlConnection. The MySqlConnection is opened and set as the Connection for the MySqlCommand. The example then calls ExecuteNonQuery, and closes the connection. To accomplish this, the ExecuteNonQuery is passed a connection string and a query string that is an SQL INSERT statement.

26.2.3.1.3.1. VB.NET

The following example show how to use the MySqlCommand class with VB.NET:

```
Public Sub InsertRow(myConnectionString As String)
    ' If the connection string is null, use a default.
    If myConnectionString = "" Then
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    End If
    Dim myConnection As New MySqlConnection(myConnectionString)
    Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) 
    Dim myCommand As New MySqlCommand(myInsertQuery)
    myCommand.Connection = myConnection
    myConnection.Open()
    myCommand.ExecuteNonQuery()
    myCommand.Connection.Close()
End Sub
```

26.2.3.1.3.2. C#

The following example show how to use the MySqlCommand class with C#:

```
public void InsertRow(string myConnectionString)
{
    // If the connection string is null, use a default.
    if(myConnectionString == "")
    {
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    }
    MySqlConnection myConnection = new MySqlConnection(myConnectionString);
    string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(
    MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
    myCommand.Connection = myConnection;
    myConnection.Open();
    myCommand.ExecuteNonQuery();
    myCommand.Connection.Close();
}
```

26.2.3.2. The MySqlCommandBuilder Class

The MySqlDataAdapter does not automatically generate the SQL statements required to reconcile changes made to a DataSet with the associated instance of MySQL. However, you can create a MySqlCommandBuilder object to automatically generate SQL statements for single-table updates if you set the SelectCommand property of the MySqlDataAdapter. Then, any additional SQL statements that you do not set are generated by the MySqlCommandBuilder.

The MySqlCommandBuilder registers itself as a listener for OnRowUpdating events whenever you set the DataAdapter property. You can only associate one MySqlDataAdapter or MySqlCommandBuilder object with each other at one time.

To generate INSERT, UPDATE, or DELETE statements, the MySqlCommandBuilder uses the SelectCommand property to retrieve a required set of metadata automatically. If you change the SelectCommand after the metadata has is retrieved (for example, after the first update), you should call the RefreshSchema method to update the metadata.

The SelectCommand must also return at least one primary key or unique column. If none are present, an InvalidOperation exception is generated, and the commands are not generated.

The MySqlCommandBuilder also uses the Connection, CommandTimeout, and Transaction properties referenced by the SelectCommand. The user should call RefreshSchema if any of these properties are modified, or if the SelectCommand itself is replaced. Otherwise the InsertCommand, UpdateCommand, and DeleteCommand properties retain their previous values.

If you call Dispose, the MySqlCommandBuilder is disassociated from the MySqlDataAdapter, and the generated commands are no longer used.

26.2.3.2.1. Properties

The following properties are available:

- `DataAdapter`: The MySqlCommandBuilder registers itself as a listener for RowUpdating events that are generated by the MySqlDataAdapter specified in this property. When you create a new instance MySqlCommandBuilder, any existing MySqlCommandBuilder associated with this MySqlDataAdapter is released.
- `QuotePrefix`, `QuoteSuffix`: Database objects in MySQL can contain special characters such as spaces that would make normal SQL strings impossible to correctly parse. Use of the QuotePrefix and the QuoteSuffix properties allows the MySqlCommandBuilder to build SQL commands that handle this situation.

26.2.3.2.2. Methods

The following methods are available:

- `DeriveParameters`: Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.
- `GetDeleteCommand`: Gets the automatically generated MySqlCommand object required to perform deletions on the database.
- `GetInsertCommand`: Gets the automatically generated MySqlCommand object required to perform insertions on the database.
- `GetUpdateCommand`: Gets the automatically generated MySqlCommand object required to perform updates on the database.
- `RefreshSchema`: Refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements.

26.2.3.2.3. Usage

The following example uses the MySqlCommand, along MySqlDataAdapter and MySqlConnection, to select rows from a data source. The example is passed an initialized DataSet, a connection string, a query string that is an SQL SELECT statement, and a string that is the name of the database table. The example then creates a MySqlCommandBuilder.

26.2.3.2.3.1. VB.NET

The following example shows how to use the MySqlCommandBuilder class with VB.NET:

```
  Public Shared Function SelectRows(myConnection As String, mySelectQuery As St
        Dim myConn As New MySqlConnection(myConnection)
        Dim myDataAdapter As New MySqlDataAdapter()
        myDataAdapter.SelectCommand = New MySqlCommand(mySelectQuery, myConn)
        Dim cb As SqlCommandBuilder = New MySqlCommandBuilder(myDataAdapter)

        myConn.Open()

        Dim ds As DataSet = New DataSet
        myDataAdapter.Fill(ds, myTableName)

        ' Code to modify data in DataSet here

        ' Without the MySqlCommandBuilder this line would fail.
        myDataAdapter.Update(ds, myTableName)

        myConn.Close()
    End Function 'SelectRows
```

26.2.3.2.3.2. C#

The following example shows how to use the MySqlCommandBuilder class with C#:

```
    public static DataSet SelectRows(string myConnection, string mySelectQuery,
    {
      MySqlConnection myConn = new MySqlConnection(myConnection);
      MySqlDataAdapter myDataAdapter = new MySqlDataAdapter();
      myDataAdapter.SelectCommand = new MySqlCommand(mySelectQuery, myConn);
      MySqlCommandBuilder cb = new MySqlCommandBuilder(myDataAdapter);

      myConn.Open();
```

```
    DataSet ds = new DataSet();
    myDataAdapter.Fill(ds, myTableName);

    //code to modify data in DataSet here

    //Without the MySqlCommandBuilder this line would fail
    myDataAdapter.Update(ds, myTableName);

    myConn.Close();

    return ds;
  }
```

26.2.3.3. The MySqlConnection Class

A MySqlConnection object represents a session to a MySQL Server data source. When you create an instance of MySqlConnection, all properties are set to their initial values. For a list of these values, see the MySqlConnection constructor.

If the MySqlConnection goes out of scope, it is not closed. Therefore, you must explicitly close the connection by calling Close or Dispose.

26.2.3.3.1. Properties

The following properties are available:

- `ConnectionString`: Gets or sets the string used to connect to a MySQL Server database.
- `ConnectionTimeout`: Gets the time to wait while trying to establish a connection before terminating the attempt and generating an error.
- `Database`: Gets the name of the current database or the database to be used after a connection is opened.
- `DataSource`: Gets the name of the MySQL server to which to connect.
- `ServerThread`: Returns the id of the server thread this connection is executing on.
- `ServerVersion`: Gets a string containing the version of the MySQL server to which the client is connected.
- `State`: Gets the current state of the connection.
- `UseConnection`: Indicates if this connection should use compression when communicating with the server.

26.2.3.3.2. Methods

The following methods are available:

- `BeginTransaction`: Begins a database transaction.
- `ChangeDatabase`: Changes the current database for an open MySqlConnection.
- `Close`: Closes the connection to the database. This is the preferred method of closing any open connection.
- `CreateCommand`: Creates and returns a MySqlCommand object associated with the MySqlConnection.

- `Dispose`: Releases the resources used by the MySqlConnection.
- `Open`: Opens a database connection with the property settings specified by the Connection-String.
- `Ping`: Pings the MySQL server.

26.2.3.3.3. Usage

The following example creates a MySqlCommand and a MySqlConnection. The MySqlConnection is opened and set as the Connection for the MySqlCommand. The example then calls ExecuteNon-Query, and closes the connection. To accomplish this, the ExecuteNonQuery is passed a connection string and a query string that is an SQL INSERT statement.

26.2.3.3.3.1. VB.NET

The following example shows how to use the MySqlConnection class with VB.NET:

```
Public Sub InsertRow(myConnectionString As String)
    ' If the connection string is null, use a default.
    If myConnectionString = "" Then
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    End If
    Dim myConnection As New MySqlConnection(myConnectionString)
    Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) 
    Dim myCommand As New MySqlCommand(myInsertQuery)
    myCommand.Connection = myConnection
    myConnection.Open()
    myCommand.ExecuteNonQuery()
    myCommand.Connection.Close()
End Sub
```

26.2.3.3.3.2. C#

The following example shows how to use the MySqlConnection class with C#:

```
public void InsertRow(string myConnectionString)
{
    // If the connection string is null, use a default.
    if(myConnectionString == "")
    {
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    }
    MySqlConnection myConnection = new MySqlConnection(myConnectionString);
    string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(
    MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
    myCommand.Connection = myConnection;
    myConnection.Open();
    myCommand.ExecuteNonQuery();
    myCommand.Connection.Close();
}
```

26.2.3.4. The MySqlDataAdapter Class

The MySQLDataAdapter serves as a bridge between a DataSet and MySQL for retrieving and saving data. The MySQLDataAdapter provides this bridge by mapping Fill, which changes the data in the DataSet to match the data in the data source, and Update, which changes the data in the data source to match the data in the DataSet, using the appropriate SQL statements against the data source.

When the MySQLDataAdapter fills a DataSet, it will create the necessary tables and columns for the returned data if they do not already exist. However, primary key information will not be included in the implicitly created schema unless the MissingSchemaAction property is set to AddWithKey. You may also have the MySQLDataAdapter create the schema of the DataSet, including primary key information, before filling it with data using FillSchema.

MySQLDataAdapter is used in conjunction with MySqlConnection and MySqlCommand to increase performance when connecting to a MySQL database.

The MySQLDataAdapter also includes the SelectCommand, InsertCommand, DeleteCommand, UpdateCommand, and TableMappings properties to facilitate the loading and updating of data.

26.2.3.4.1. Properties

The following properties are available:

- `AcceptChangesDuringFill`: Gets or sets a value indicating whether AcceptChanges is called on a DataRow after it is added to the DataTable during any of the Fill operations.
- `ContinueUpdateOnError`: Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
- `DeleteCommand`: Gets or sets an SQL statement or stored procedure used to delete records from the data set.
- `InsertCommand`: Gets or sets an SQL statement or stored procedure used to insert records into the data set.
- `MissingMappingAction`: Determines the action to take when incoming data does not have a matching table or column.
- `MissingSchemaAction`: Determines the action to take when existing DataSet schema does not match incoming data.
- `SelectCommand`: Gets or sets an SQL statement or stored procedure used to select records in the data source.
- `TableMappings`: Gets a collection that provides the master mapping between a source table and a DataTable.
- `UpdateCommand`: Gets or sets an SQL statement or stored procedure used to updated records in the data source.

26.2.3.4.2. Methods

The following methods are available:

- `Fill`: Adds or refreshes rows in the DataSet to match those in the data source using the DataSet name, and creates a DataTable named "Table".
- `FillSchema`: Adds a DataTable named "Table" to the specified DataSet and configures the schema to match that in the data source based on the specified SchemaType.
- `GetFillParameters`: Gets the parameters set by the user when executing an SQL SELECT statement.
- `Update`: Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.

26.2.3.4.3. Usage

The following example creates a MySqlCommand and a MySqlConnection. The MySqlConnection is opened and set as the Connection for the MySqlCommand. The example then calls ExecuteNonQuery, and closes the connection. To accomplish this, the ExecuteNonQuery is passed a connection string and a query string that is an SQL INSERT statement.

26.2.3.4.3.1. VB.NET

The following example shows how to use the MySqlDataAdapter class with VB.NET:

```
Public Function SelectRows(dataSet As DataSet, connection As String, query As S
    Dim conn As New MySqlConnection(connection)
    Dim adapter As New MySqlDataAdapter()
    adapter.SelectCommand = new MySqlCommand(query, conn)
    adapter.Fill(dataset)
    Return dataset
End Function
```

26.2.3.4.3.2. C#

The following example shows how to use the MySqlDataAdapter class with C#:

```
public DataSet SelectRows(DataSet dataset,string connection,string query)
{
    MySqlConnection conn = new MySqlConnection(connection);
    MySqlDataAdapter adapter = new MySqlDataAdapter();
    adapter.SelectCommand = new MySqlCommand(query, conn);
    adapter.Fill(dataset);
    return dataset;
}
```

26.2.3.5. The MySqlDataReader Class

The MySqlDataReader class provides a means of reading a forward-only stream of rows from a MySQL database.

To create a MySQLDataReader, you must call the ExecuteReader method of the MySqlCommand object, rather than directly using a constructor.

While the MySqlDataReader is in use, the associated MySqlConnection is busy serving the MySqlDataReader, and no other operations can be performed on the MySqlConnection other than closing it. This is the case until the Close method of the MySqlDataReader is called.

IsClosed and RecordsAffected are the only properties that you can call after the MySqlDataReader is closed. Though the RecordsAffected property may be accessed at any time while the MySqlDataReader exists, always call Close before returning the value of RecordsAffected to ensure an accurate return value.

For optimal performance, MySqlDataReader avoids creating unnecessary objects or making unnecessary copies of data. As a result, multiple calls to methods such as GetValue return a reference to the same object. Use caution if you are modifying the underlying value of the objects returned by methods such as GetValue.

26.2.3.5.1. Properties

The following properties are available:

- `Depth`: Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

- `FieldCount`: Gets the number of columns in the current row.
- `HasRows`: Gets a value indicating whether the MySqlDataReader contains one or more rows.
- `IsClosed`: Gets a value indicating whether the data reader is closed.
- `Item`: Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.
- `RecordsAffected`: Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

26.2.3.5.2. Methods

The following methods are available:

- `Close`: Closes the MySqlDataReader object.
- `GetBoolean`: Gets the value of the specified column as a Boolean.
- `GetByte`: Gets the value of the specified column as a byte.
- `GetBytes`: Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
- `GetChar`: Gets the value of the specified column as a single character.
- `GetChars`: Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
- `GetDataTypeName`: Gets the name of the source data type.
- `GetDateTime`: Gets the value of the specified column as a DateTime object.
- `GetDecimal`: Gets the value of the specified column as a Decimal object.
- `GetDouble`: Gets the value of the specified column as a double-precision floating point number.
- `GetFieldType`: Gets the Type that is the data type of the object.
- `GetFloat`: Gets the value of the specified column as a single-precision floating point number.
- `GetGuid`: Gets the value of the specified column as a GUID.
- `GetInt16`: Gets the value of the specified column as a 16-bit signed integer.
- `GetInt32`: Gets the value of the specified column as a 32-bit signed integer.
- `GetInt64`: Gets the value of the specified column as a 64-bit signed integer.
- `GetMySqlDateTime`: Gets the value of the specified column as a MySqlDateTime object.
- `GetName`: Gets the name of the specified column.
- `GetOrdinal`: Gets the column ordinal, given the name of the column.
- `GetSchemaTable`: Returns a DataTable that describes the column metadata of the MySqlDataReader.
- `GetString`: Gets the value of the specified column as a String object.

- `GetTimeSpan`: Gets the value of the specified column as a TimeSpan object.
- `GetUInt16`: Gets the value of the specified column as a 16-bit unsigned integer.
- `GetUInt32`: Gets the value of the specified column as a 32-bit unsigned integer.
- `GetUInt64`: Gets the value of the specified column as a 64-bit unsigned integer.
- `GetValue`: Gets the value of the specified column in its native format.
- `GetValues`: Gets all attribute columns in the collection for the current row.
- `IsDBNull`: Gets a value indicating whether the column contains non-existent or missing values.
- `NextResult`: Advances the data reader to the next result, when reading the results of batch SQL statements.
- `Read`: Advances the MySqlDataReader to the next record.

26.2.3.5.3. Usage

The following example creates a MySqlConnection, a MySqlCommand, and a MySqlDataReader. The example reads through the data, writing it out to the console. Finally, the example closes the MySqlDataReader, then the MySqlConnection

26.2.3.5.3.1. VB.NET

The following example shows how to use the MySqlDataReader class with VB.NET:

```
Public Sub ReadMyData(myConnString As String)
    Dim mySelectQuery As String = "SELECT OrderID, CustomerID FROM Orders"
    Dim myConnection As New MySqlConnection(myConnString)
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
    myConnection.Open()
    Dim myReader As MySqlDataReader
    myReader = myCommand.ExecuteReader()
    ' Always call Read before accessing data.
    While myReader.Read()
        Console.WriteLine((myReader.GetInt32(0) & ", " & myReader.GetString(1))
    End While
    ' always call Close when done reading.
    myReader.Close()
    ' Close the connection when done with it.
    myConnection.Close()
End Sub 'ReadMyData
```

26.2.3.5.3.2. C#

The following example shows how to use the MySqlDataReader class with C#:

```
public void ReadMyData(string myConnString) {
    string mySelectQuery = "SELECT OrderID, CustomerID FROM Orders";
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery,myConnection);
    myConnection.Open();
    MySqlDataReader myReader;
    myReader = myCommand.ExecuteReader();
    // Always call Read before accessing data.
    while (myReader.Read()) {
       Console.WriteLine(myReader.GetInt32(0) + ", " + myReader.GetString(1));
    }
    // always call Close when done reading.
```

```
    myReader.Close();
    // Close the connection when done with it.
    myConnection.Close();
 }
```

26.2.3.6. The MySqlException Class

This class is created whenever the MySql Data Provider encounters an error generated from the server.

Any open connections are not automatically closed when an exception is thrown. If the client application determines that the exception is fatal, it should close any open MySqlDataReader objects or MySqlConnection objects.

26.2.3.6.1. Properties

The following properties are available:

- `HelpLink`: Gets or sets a link to the help file associated with this exception.
- `InnerException`: Gets the Exception instance that caused the current exception.
- `IsFatal`: True if this exception was fatal and cause the closing of the connection, false otherwise.
- `Message`: Gets a message that describes the current exception.
- `Number`: Gets a number that identifies the type of error.
- `Source`: Gets or sets the name of the application or the object that causes the error.
- `StackTrace`: Gets a string representation of the frames on the call stack at the time the current exception was thrown.
- `TargetSite`: Gets the method that throws the current exception.

26.2.3.6.2. Methods

The MySqlException class has no methods.

26.2.3.6.3. Usage

The following example generates a MySqlException due to a missing server, and then displays the exception.

26.2.3.6.3.1. VB.NET

This example demonstrates how to use the MySqlException class with VB.NET:

```
Public Sub ShowException()
     Dim mySelectQuery As String = "SELECT column1 FROM table1"
     Dim myConnection As New MySqlConnection ("Data Source=localhost;Database=S
     Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)

     Try
         myCommand.Connection.Open()
     Catch e As MySqlException
        MessageBox.Show( e.Message )
     End Try
 End Sub
```

26.2.3.6.3.2. C#

This example demonstrates how to use the MySqlException class with C#:

```
public void ShowException()
{
   string mySelectQuery = "SELECT column1 FROM table1";
   MySqlConnection myConnection =
      new MySqlConnection("Data Source=localhost;Database=Sample;");
   MySqlCommand myCommand = new MySqlCommand(mySelectQuery,myConnection);

   try
   {
      myCommand.Connection.Open();
   }
   catch (MySqlException e)
   {
       MessageBox.Show( e.Message );
   }
}
```

26.2.3.7. The MySqlHelper Class

Helper class that makes it easier to work with the provider. Developers can use the methods of this class to automatically perform common tasks.

26.2.3.7.1. Properties

The MySqlHelper class has no properties.

26.2.3.7.2. Methods

The following methods are available:

- `ExecuteDataRow`: Executes a single SQL command and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.
- `ExecuteDataset`: Executes a single SQL command and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.
- `ExecuteNonQuery`: Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.
- `ExecuteReader`: Overloaded. Executes a single command against a MySQL database.
- `ExecuteScalar`: Execute a single command against a MySQL database.
- `UpdateDataSet`: Updates the given table with data from the given DataSet.

26.2.3.8. The MySqlTransaction Class

Represents an SQL transaction to be made in a MySQL database.

26.2.3.8.1. Properties

The following properties are available:

- `Connection`: Gets the MySqlConnection object associated with the transaction, or a null ref-

erence (Nothing in Visual Basic) if the transaction is no longer valid.

- `IsolationLevel`: Specifies the IsolationLevel for this transaction.

26.2.3.8.2. Methods

The following methods are available:

- `Commit`: Commits the database transaction.
- `Rollback`: Rolls back a transaction from a pending state.

26.2.3.8.3. Usage

The following example creates a MySqlConnection and a MySqlTransaction. It also demonstrates how to use the BeginTransaction, Commit, and Rollback methods.

26.2.3.8.3.1. VB.NET

The following example shows how to use the MySqlTransaction class with VB.NET:

```
Public Sub RunTransaction(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()

    Dim myCommand As MySqlCommand = myConnection.CreateCommand()
    Dim myTrans As MySqlTransaction

    ' Start a local transaction
    myTrans = myConnection.BeginTransaction()
    ' Must assign both transaction object and connection
    ' to Command object for a pending local transaction
    myCommand.Connection = myConnection
    myCommand.Transaction = myTrans

    Try
      myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)
      myCommand.ExecuteNonQuery()
      myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)
      myCommand.ExecuteNonQuery()
      myTrans.Commit()
      Console.WriteLine("Both records are written to database.")
    Catch e As Exception
      Try
        myTrans.Rollback()
      Catch ex As MySqlException
        If Not myTrans.Connection Is Nothing Then
          Console.WriteLine("An exception of type " & ex.GetType().ToString() &
                            " was encountered while attempting to roll back the
        End If
      End Try

      Console.WriteLine("An exception of type " & e.GetType().ToString() & _
                        "was encountered while inserting the data.")
      Console.WriteLine("Neither record was written to database.")
    Finally
      myConnection.Close()
    End Try
End Sub 'RunTransaction
```

26.2.3.8.3.2. C#

The following example shows how to use the MySqlTransaction class with C#:

```
public void RunTransaction(string myConnString)
 {
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();

    MySqlCommand myCommand = myConnection.CreateCommand();
    MySqlTransaction myTrans;

    // Start a local transaction
    myTrans = myConnection.BeginTransaction();
    // Must assign both transaction object and connection
    // to Command object for a pending local transaction
    myCommand.Connection = myConnection;
    myCommand.Transaction = myTrans;

    try
    {
      myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)
      myCommand.ExecuteNonQuery();
      myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)
      myCommand.ExecuteNonQuery();
      myTrans.Commit();
      Console.WriteLine("Both records are written to database.");
    }
    catch(Exception e)
    {
      try
      {
        myTrans.Rollback();
      }
      catch (MySqlException ex)
      {
        if (myTrans.Connection != null)
        {
          Console.WriteLine("An exception of type " + ex.GetType() +
                            " was encountered while attempting to roll back the
        }
      }

      Console.WriteLine("An exception of type " + e.GetType() +
                        " was encountered while inserting the data.");
      Console.WriteLine("Neither record was written to database.");
    }
    finally
    {
      myConnection.Close();
    }
}
```

26.2.4. Using MySQL Connector/NET

26.2.4.1. Introduction

In this section we will cover some of the more common use cases for Connector/NET, including BLOB handling, date handling, and using Connector/NET with common tools such as Crystal Reports.

26.2.4.2. Connecting to MySQL Using MySQL Connector/NET

26.2.4.2.1. Introduction

All interaction between a .NET application and the MySQL server is routed through a `MySqlCon-`

nection object. Before your application can interact with the server, a MySqlConnection object must be instanced, configured, and opened.

Even when using the MySqlHelper class, a MySqlConnection object is created by the helper class.

In this section, we will describe how to connect to MySQL using the MySqlConnection object.

26.2.4.2.2. Creating a Connection String

The MySqlConnection object is configured using a connection string. A connection string contains sever key/value pairs, separated by semicolons. Each key/value pair is joined with an equals sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the MySqlConnection object is configured to connect to a MySQL server at 127.0.0.1, with a username of root and a password of 12345. The default database for all statements will be the test database.

The following options are typically used (a full list of options is available in the API documentation):

- Server: The name or network address of the instance of MySQL to which to connect. The default is localhost. Aliases include host, Data Source, DataSource, Address, Addr and Network Address.
- Uid: The MySQL user account to use when connecting. Aliases include User Id, Username and User name.
- Pwd: The password for the MySQL account being used. Alias Password can also be used.
- Database: The default database that all statements are applied to. Default is mysql. Alias Initial Catalog can also be used.
- Port: The port MySQL is using to listen for connections. Default is 3306. Specify -1 for this value to use a named pipe connection.

26.2.4.2.3. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a MySqlConnection object, assign the connection string, and open the connection.

[VB]

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
            & "uid=root;" _
            & "pwd=12345;" _
            & "database=test;"

Try
  conn.ConnectionString = myConnectionString
  conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
```

```
  MessageBox.Show(ex.Message)
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

[VB]

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
              & "uid=root;" _
              & "pwd=12345;" _
              & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
   MessageBox.Show(ex.Message)
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other MySQL Connector/NET classes to communicate with the MySQL server.

26.2.4.2.4. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- `Message`: A message that describes the current exception.
- `Number`: The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- `0`: Cannot connect to server.
- `1045`: Invalid username and/or password.

The following code shows how to adapt the application's response based on the actual error:

[VB]

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
          & "uid=root;" _
          & "pwd=12345;" _
          & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
    catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server.  Contact administrator");
        case 1045:
            MessageBox.Show("Invalid username/password, please try again");
    }
```

```
}
```

26.2.4.3. Using the MySQL Connector/NET with Prepared Statements

26.2.4.3.1. Introduction

As of MySQL 4.1, it is possible to use prepared statements with MySQL Connector/NET. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

26.2.4.3.2. Preparing Statements in MySQL Connector/NET

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySqlCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
   conn.Open()
   cmd.Connection = conn

   cmd.CommandText = "INSERT INTO myTable VALUES(NULL, ?number, ?text)"
   cmd.Prepare()

   cmd.Parameters.Add("?number", 1)
   cmd.Parameters.Add("?text", "One")

   For i = 1 To 1000
       cmd.Parameters("?number").Value = i
       cmd.Parameters("?text").Value = "A string value"

       cmd.ExecuteNonQuery()
     Next
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Err
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, ?number, ?text)";
    cmd.Prepare();

    cmd.Parameters.Add("?number", 1);
    cmd.Parameters.Add("?text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["?number"].Value = i;
        cmd.Parameters["?text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

26.2.4.4. Accessing Stored Procedures with MySQL Connector/NET

26.2.4.4.1. Introduction

With the release of MySQL version 5 the MySQL server now supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Stored procedures can be particularly useful in situations such as the following:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

MySQL Connector/NET supports the calling of stored procedures through the `MySqlCommand` object. Data can be passed in and our of a MySQL stored procedure through use of the `MySqlCommand.Parameters` collection.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to http://dev.mysql.com/doc/mysql/en/stored-procedures.html.

A sample application demonstrating how to use stored procedures with MySQL Connector/NET can be found in the `Samples` directory of your MySQL Connector/NET installation.

26.2.4.4.2. Creating Stored Procedures from MySQL Connector/NET

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using the `MySQL Query Browser` GUI client. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "CREATE PROCEDURE add_emp(" _
        & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT em
        & "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " _
        & "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END"

    cmd.ExecuteNonQuery()
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Err
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "CREATE PROCEDURE add_emp(" +
        "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empn
        "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
        "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

    cmd.ExecuteNonQuery();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
    "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It should be noted that, unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in MySQL Connector/NET.

26.2.4.4.3. Calling a Stored Procedure from MySQL Connector/NET

To call a stored procedure using MySQL Connector/NET, create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. Set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the datatype that is expected to be returned. All parameters need the parameter direction defined.

After defining parameters, call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "add_emp"
    cmd.CommandType = CommandType.StoredProcedure

    cmd.Parameters.Add("?lname", 'Jones')
    cmd.Parameters("?lname").Direction = ParameterDirection.Input

    cmd.Parameters.Add("?fname", 'Tom')
    cmd.Parameters("?fname").Direction = ParameterDirection.Input

    cmd.Parameters.Add("?bday", #12/13/1977 2:17:36 PM#)
    cmd.Parameters("?bday").Direction = ParameterDirection.Input

    cmd.Parameters.Add("?empno", MySqlDbType.Int32)
    cmd.Parameters("?empno").Direction = ParameterDirection.Output

    cmd.ExecuteNonQuery()

    MessageBox.Show(cmd.Parameters("?empno").Value)
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Err
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn.Open();
    cmd.Connection = conn;
```

```
    cmd.CommandText = "add_emp";
    cmd.CommandType = CommandType.StoredProcedure;

    cmd.Parameters.Add("?lname", "Jones");
    cmd.Parameters("?lname").Direction = ParameterDirection.Input;

    cmd.Parameters.Add("?fname", "Tom");
    cmd.Parameters("?fname").Direction = ParameterDirection.Input;

    cmd.Parameters.Add("?bday", DateTime.Parse("12/13/1977 2:17:36 PM"));
    cmd.Parameters("?bday").Direction = ParameterDirection.Input;

    cmd.Parameters.Add("?empno", MySqlDbType.Int32);
    cmd.Parameters("?empno").Direction = ParameterDirection.Output;

    cmd.ExecuteNonQuery();

    MessageBox.Show(cmd.Parameters("?empno").Value);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
      "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

Once the stored procedure is called, the values of output parameters can be retrieved by using the `.Value` property of the `MySqlConnector.Parameters` collection.

26.2.4.5. Handling BLOB Data With Connector/NET

26.2.4.5.1. Introduction

One common use for MySQL is the storage of binary data in `BLOB` columns. MySQL supports four different BLOB datatypes: `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`.

Data stored in a BLOB column can be accessed using Connector/NET and manipulated using client-side code. There are no special requirements for using Connector/NET with BLOB data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the MySQL Connector/NET installation.

26.2.4.5.2. Preparing the MySQL Server

The first step is using MySQL with BLOB data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an AUTO_INCREMENT column of appropriate size (UNSIGNED SMALLINT) to serve as a primary key to identify the file, a VARCHAR column that stores the filename, an UNSIGNED MEDIUMINT column that stores the size of the file, and a MEDIUMBLOB column that stores the file itself. For this example, I will use the following table definition:

```
CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);
```

After creating a table, you may need to modify the max_allowed_packet system variable. This variable determines how large of a packet (i.e. a single row) can be sent to the MySQL server. By default, the server will only accept a maximum size of 1 meg from our client application. If you do not intend to exceed 1 meg, this should be fine. If you do intend to exceed 1 meg in your file transfers, this number has to be increased.

The max_allowed_packet option can be modified using MySQL Administrator's Startup Variables

screen. Adjust the Maximum allowed option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the Apply Changes button and restart the server using the `Service Control` screen of MySQL Administrator. You can also adjust this value directly in the my.cnf file (add a line that reads max_allowed_packet=xxM), or use the SET max_allowed_packet=xxM; syntax from within MySQL.

Try to be conservative when setting max_allowed_packet, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

26.2.4.5.3. Writing a File to the Database

To write a file to a database we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a FileStream object, reads it into a byte array, and inserts it into the `file` table:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim FileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
    FileSize = fs.Length

    rawData = New Byte(FileSize) {}
    fs.Read(rawData, 0, FileSize)
    fs.Close()

    conn.Open()

    SQL = "INSERT INTO file VALUES(NULL, ?FileName, ?FileSize, ?File)"

    cmd.Connection = conn
    cmd.CommandText = SQL
    cmd.Parameters.Add("?FileName", strFileName)
    cmd.Parameters.Add("?FileSize", FileSize)
    cmd.Parameters.Add("?File", rawData)

    cmd.ExecuteNonQuery()

    MessageBox.Show("File Inserted into database successfully!", _
    "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", _
        MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, ?FileName, ?FileSize, ?File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.Add("?FileName", strFileName);
    cmd.Parameters.Add("?FileSize", FileSize);
    cmd.Parameters.Add("?File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the FileStream object.

After assigning the byte array as a parameter of the `MySqlCommand` object, the `ExecuteNonQuery` method is called and the BLOB is inserted into the `file` table.

26.2.4.5.4. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySqlDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySqlDataReader
Dim SQL As String
Dim rawData() As Byte
```

```
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save"

    myData.Read()

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(FileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Wri
    fs.Write(rawData, 0, FileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBo

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxBut
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataReader myData;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
    conn.Open();

    cmd.Connection = conn;
    cmd.CommandText = SQL;

    myData = cmd.ExecuteReader();
```

```
    if (! myData.HasRows)
        throw new Exception("There are no BLOBs to save");

    myData.Read();

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
    rawData = new byte[FileSize];

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize);

    fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Wr
    fs.Write(rawData, 0, FileSize);
    fs.Close();

    MessageBox.Show("File successfully written to disk!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    myData.Close();
    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the MySqlDataReader is used to load the BLOB into a byte array, which is then written to disk using a FileStream object.

The `GetOrdinal` method of the MySqlDataReader can be used to determine the integer index of a named column. Use of the GetOrdinal method prevents errors if the column order of the SELECT query is changed.

26.2.4.6. Using MySQL Connector/NET with Crystal Reports

26.2.4.6.1. Introduction

Crystal Reports is a common tool used by Windows application developers to perform reporting an document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/NET.

Complete sample applications are available in the CrystalDemo subdirectory of the Samples directory of your MySQL Connector/NET installation.

26.2.4.6.2. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a dataset that matches the one expected by your report.

The second option is to create a dataset in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the dataset. If you forget a column you must re-create the dataset before the column can be added to the report.

The following code can be used to create a dataset from a query and write it to disk:

[VB]

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPop
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButton
End Try
```

[C#]

```
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
  "pwd=12345;database=test;";

try
{
  cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopul
  "country.name, country.population, country.continent " +
  "FROM country, city ORDER BY country.continent, country.name";
  cmd.Connection = conn;

  myAdapter.SelectCommand = cmd;
  myAdapter.Fill(myData);

  myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
  MessageBox.Show(ex.Message, "Report could not be created",
  MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from dev.mysql.com [http://dev.mysql.com/downloads/connector/odbc/3.51.html].

26.2.4.6.3. Creating the Report

For most purposes the Standard Report wizard should help with the initial creation of a report. To start the wizard, open Crystal Reports and choose the New > Standard Report option from the File menu.

The wizard will first prompt you for a data source. If you are using Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved dataset, choose the ADO.NET (XML) option and browse to your saved dataset.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

26.2.4.6.4. Displaying the Report

To display a report we first populate a dataset with the data needed for the report, then load the report and bind it to the dataset. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrytalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a dataset saved using the code shown in Creating a Data Source and have a crViewer control on your form named `myViewer`.

[VB]

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
    "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()

    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPop
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
```

```
    myReport.SetDataSource(myData)
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButton
End Try
```

[C#]

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPop
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.SetDataSource(myData);
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

A new dataset it generated using the same query used to generate the previously saved dataset. Once the dataset is filled, a ReportDocument is used to load the report file and bind it to the dataset. The ReportDocument is the passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The dataset replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a dataset with multiple tables must be created in our application. This allows each table in the report data source to be replaced with a report in the dataset.

We populate a dataset with multiple tables by providing multiple SELECT statements in our MySql-Command object. These SELECT statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```
SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `coun
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`
```

This query is converted to two SELECT queries and displayed with the following code:

[VB]

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY
        & "SELECT name, population, code, continent FROM country ORDER BY conti
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButton
End Try
```

[C#]

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
        "BY countrycode, name; SELECT name, population, code, continent FROM " +
        "country ORDER BY continent, name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
    myViewer.ReportSource = myReport;
}
```

```
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It is important to order the SELECT queries in alphabetical order, as this is the order the report will expect its source tables to be in. One SetDataSource statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved dataset.

26.2.4.7. Handling Date and Time Information in MySQL Connector/NET

26.2.4.7.1. Introduction

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '`0000-00-00 00:00:00`'. These differences can cause problems if not properly handled.

In this section we will demonstrate how to properly handle date and time information when using MySQL Connector/NET.

26.2.4.7.2. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

26.2.4.7.3. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see Section 5.3.2, “The Server SQL Mode”.

26.2.4.7.4. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` datatype.

The `MySqlDateTime` datatype supports the same date values that are supported by the MySQL server. The default behavior of MySQL Connector/NET is to return a .NET DateTime object for valid date values, and return an error for invalid dates. This default can be modified to cause MySQL Connector/NET to return `MySqlDateTime` objects for invalid dates.

To instruct MySQL Connector/NET to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, `2005-02-23 08:50:25`). This differs from the `ToString` behavior of the .NET DateTime class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET DateTime class does not. This can cause errors when trying to convert a MySQLDateTime to a DateTime if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

26.2.4.7.5. Handling NULL Dates

The .NET `DateTime` datatype cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

[VB]

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
End If
```

[C#]

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

`NULL` values will work in a dataset and can be bound to form controls without special handling.

26.2.5. MySQL Connector/NET Change History

26.2.5.1. Version 1.0.7

- The parameter collection object's `Add()` method added parameters to the list without first checking to see if the they already existed. Now it updates the value of the existing parameter object if it exists. (Bug #13927 [http://bugs.mysql.com/13927])
- A `#42000Query was empty` exception occurred when executing a query built with `MySqlCommandBuilder`, if the query string ended with a semicolon. (Bug #14631 [http://bugs.mysql.com/14631])

- Implemented the `MySqlCommandBuilder.DeriveParameters` method that is used to discover the parameters for a stored procedure. (Bug #13632 [http://bugs.mysql.com/13632])
- Added support for the `cp932` character set. (Bug #13806 [http://bugs.mysql.com/13806])
- Calling a stored procedure where a parameter contained special characters (such as `'@'`) would produce an exception. Note that `ANSI_QUOTES` had to be enabled to make this possible. (Bug #13753 [http://bugs.mysql.com/13753])
- A statement that contained multiple references to the same parameter could not be prepared. (Bug #13541 [http://bugs.mysql.com/13541])
- The `Ping()` method did not update the `State` property of the `Connection` object. (Bug #13658 [http://bugs.mysql.com/13658])

26.2.5.2. Version 1.0.6

- The `nant` build sequence had problems. (Bug #12978 [http://bugs.mysql.com/12978])
- Serializing a parameter failed if the first value passed in was `NULL`. (Bug #13276 [http://bugs.mysql.com/13276])
- Field names that contained the following characters caused errors: `()%<>/` (Bug #13036 [http://bugs.mysql.com/13036])
- The MySQL Connector/NET 1.0.5 installer would not install alongside MySQL Connector/NET 1.0.4. (Bug #12835 [http://bugs.mysql.com/12835])
- MySQL Connector/NET 1.0.5 could not connect on Mono. (Bug #13345 [http://bugs.mysql.com/13345])

26.2.5.3. Version 1.0.5

- With multiple hosts in the connection string, MySQL Connector/NET would not connect to the last host in the list. (Bug #12628 [http://bugs.mysql.com/12628])
- MySQL Connector/NET interpreted the new decimal data type as a byte array. (Bug #11294 [http://bugs.mysql.com/11294])
- The `cp1250` character set was not supported. (Bug #11621 [http://bugs.mysql.com/11621])
- Connection could fail when .NET thread pool had no available worker threads. (Bug #10637 [http://bugs.mysql.com/10637])
- Decimal parameters caused syntax errors. (Bug #11550 [http://bugs.mysql.com/11550], Bug #10486 [http://bugs.mysql.com/10486], Bug #10152 [http://bugs.mysql.com/10152])
- A call to a stored procedure caused an exception if the stored procedure had no parameters. (Bug #11542 [http://bugs.mysql.com/11542])
- Certain malformed queries would trigger a `Connection must be valid and open` error message. (Bug #11490 [http://bugs.mysql.com/11490])
- The `MySqlCommandBuilder` class could not handle queries that referenced tables in a database other than the default database. (Bug #8382 [http://bugs.mysql.com/8382])
- MySQL Connector/NET could not work properly with certain regional settings. (WL#8228)
- Trying to use a stored procedure when `Connection.Database` was not populated generated

an exception. (Bug #11450 [http://bugs.mysql.com/11450])

- Trying to read a `TIMESTAMP` column generated an exception. (Bug #7951 [http://bugs.mysql.com/7951])
- Parameters were not recognized when they were separated by linefeeds. (Bug #9722 [http://bugs.mysql.com/9722])
- Calling `MySqlConnection.clone` when a connection string had not yet been set on the original connection would generate an error. (Bug #10281 [http://bugs.mysql.com/10281])
- Added support to call a stored function from MySQL Connector/NET. (Bug #10644 [http://bugs.mysql.com/10644])
- MySQL Connector/NET could not connect to MySQL 4.1.14. (Bug #12771 [http://bugs.mysql.com/12771])
- The `ConnectionString` property could not be set when a `MySqlConnection` object was added with the designer. (Bug #12551 [http://bugs.mysql.com/12551], Bug #8724 [http://bugs.mysql.com/8724])

26.2.5.4. Version 1.0.4 1-20-05

- Bug #7243 [http://bugs.mysql.com/7243] calling prepare causing exception [fixed]
- Fixed another small problem with prepared statements
- Bug #7258 [http://bugs.mysql.com/7258] MySqlCommand.Connection returns an IDbConnection [fixed]
- Bug #7345 [http://bugs.mysql.com/7345] MySqlAdapter.Fill method throws Error message : Non-negative number required [fixed]
- Bug #7478 [http://bugs.mysql.com/7478] Clone method bug in MySqlCommand [fixed]
- Bug #7612 [http://bugs.mysql.com/7612] MySqlDataReader.GetString(index) returns non-Null value when field is Null [fixed]
- Bug #7755 [http://bugs.mysql.com/7755] MySqlReader.GetInt32 throws exception if column is unsigned [fixed]
- Bug #7704 [http://bugs.mysql.com/7704] GetBytes is working no more [fixed]
- Bug #7724 [http://bugs.mysql.com/7724] Quote character \222 not quoted in EscapeString [fixed]
- Fixed problem that causes named pipes to not work with some blob functionality
- Fixed problem with shared memory connections
- Bug #7436 [http://bugs.mysql.com/7436] Problem with Multiple resultsets... [fixed]
- Added or filled out several more topics in the API reference documentation

26.2.5.5. Version 1.0.3-gamma 12-10-04

- Made MySQL the default named pipe name
- Now SHOW COLLATION is used upon connection to retrieve the full list of charset ids

- Fixed Invalid character set index: 200 (Bug #6547 [http://bugs.mysql.com/6547])
- Installer now includes options to install into GAC and create Start Menu items
- Bug #6863 [http://bugs.mysql.com/6863] - Int64 Support in MySqlCommand Parameters [fixed]
- Connections now do not have to give a database on the connection string
- Bug #6770 [http://bugs.mysql.com/6770] - MySqlDataReader.GetChar(int i) throws IndexOutOfRange Exception [fixed]
- Fixed problem where multiple resultsets having different numbers of columns would cause a problem
- Bug #6983 [http://bugs.mysql.com/6983] Exception stack trace lost when re-throwing exceptions [fixed]
- Fixed major problem with detecting null values when using prepared statements
- Bug #6902 [http://bugs.mysql.com/6902] Errors in parsing stored procedure parameters [fixed]
- Bug #6668 [http://bugs.mysql.com/6668] Integer "out" parameter from stored procedure returned as string [fixed]
- Bug #7032 [http://bugs.mysql.com/7032] MySqlDateTime in Datatables sorting by Text, not Date. [fixed]
- Bug #7133 [http://bugs.mysql.com/7133] Invalid query string when using inout parameters [fixed]
- Bug #6831 [http://bugs.mysql.com/6831] Test suite fails with MySQL 4.0 because of case sensitivity of table names [fixed]
- Bug #7132 [http://bugs.mysql.com/7132] Inserting DateTime causes System.InvalidCastException to be thrown [fixed]
- Bug #6879 [http://bugs.mysql.com/6879] InvalidCast when using DATE_ADD-function [fixed]
- Bug #6634 [http://bugs.mysql.com/6634] An Open Connection has been Closed by the Host System [fixed]
- Added ServerThread property to MySqlConnection to expose server thread id
- Added Ping method to MySqlConnection
- Changed the name of the test suite to MySql.Data.Tests.dll

26.2.5.6. Version 1.0.2-gamma 04-11-15

- Fixed problem with MySqlBinary where string values could not be used to update extended text columns
- Fixed Installation directory ignored using custom installation (Bug #6329 [http://bugs.mysql.com/6329])
- Fixed problem where setting command text leaves the command in a prepared state
- Fixed double type handling in MySqlParameter(string parameterName, object value) (Bug #6428 [http://bugs.mysql.com/6428])
- Fixed Zero date "0000-00-00" is returned wrong when filling Dataset (Bug #6429 [http://bugs.mysql.com/6429])

- Fixed problem where calling stored procedures might cause an "Illegal mix of collations" problem.
- Added charset connection string option
- Fixed #HY000 Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (utf8_general_ (Bug #6322 [http://bugs.mysql.com/6322])
- Added the TableEditor CS and VB sample
- Fixed Charset-map for UCS-2 (Bug #6541 [http://bugs.mysql.com/6541])
- Updated the installer to include the new samples
- Fixed Long inserts take very long time (Bu #5453)
- Fixed Objects not being disposed (Bug #6649 [http://bugs.mysql.com/6649])
- Provider is now using character set specified by server as default

26.2.5.7. Version 1.0.1-beta2 04-10-27

- Fixed BUG #5602 [http://bugs.mysql.com/5602] Possible bug in MySqlParameter(string, object) constructor
- Fixed BUG #5458 [http://bugs.mysql.com/5458] Calling GetChars on a longtext column throws an exception
- Fixed BUG #5474 [http://bugs.mysql.com/5474] cannot run a stored procedure populating mysqlcommand.parameters
- Fixed BUG #5469 [http://bugs.mysql.com/5469] Setting DbType throws NullReferenceException
- Fixed problem where connector was not issuing a CMD_QUIT before closing the socket
- Fixed BUG #5392 [http://bugs.mysql.com/5392] MySqlCommand sees "?" as parameters in string literals
- Fixed problem with ConnectionInternal where a key might be added more than once
- CP1252 is now used for Latin1 only when the server is 4.1.2 and later
- Fixed BUG #5388 [http://bugs.mysql.com/5388] DataReader reports all rows as NULL if one row is NULL
- Virtualized driver subsystem so future releases could easily support client or embedded server support
- Field buffers being reused to decrease memory allocations and increase speed
- Fixed problem where using old syntax while using the interfaces caused problems
- Using PacketWriter instead of Packet for writing to streams
- Refactored compression code into CompressedStream to clean up NativeDriver
- Added test case for resetting the command text on a prepared command
- Fixed problem where MySqlParameterCollection.Add() would throw unclear exception when given a null value (Bug #5621 [http://bugs.mysql.com/5621])

- Fixed construtor initialize problems in MySqlCommand() (Bug #5613 [http://bugs.mysql.com/5613])
- Fixed Parsing the ';' char (Bug #5876 [http://bugs.mysql.com/5876])
- Fixed missing Reference in DbType setter (Bug #5897 [http://bugs.mysql.com/5897])
- Fixed System.OverflowException when using YEAR datatype (Bug #6036 [http://bugs.mysql.com/6036])
- Added Aggregate function test (wasn't really a bug)
- Fixed serializing of floating point parameters (double, numeric, single, decimal) (Bug #5900 [http://bugs.mysql.com/5900])
- IsNullable error (Bug #5796 [http://bugs.mysql.com/5796])
- Fixed problem where connection lifetime on the connect string was not being respected
- Fixed problem where Min Pool Size was not being respected
- Fixed MySqlDataReader and 'show tables from ...' behavior (Bug #5256 [http://bugs.mysql.com/5256])
- Implemented SequentialAccess
- Fixed MySqlDateTime sets IsZero property on all subseq.records after first zero found (Bug #6006 [http://bugs.mysql.com/6006])
- Fixed Can't display Chinese correctly (Bug #5288 [http://bugs.mysql.com/5288])
- Fixed Russian character support as well
- Fixed Method TokenizeSql() uses only a limited set of valid characters for parameters (Bug #6217 [http://bugs.mysql.com/6217])
- Fixed NET Connector source missing resx files (Bug #6216 [http://bugs.mysql.com/6216])
- Fixed DBNull Values causing problems with retrieving/updating queries. (Bug #5798 [http://bugs.mysql.com/5798])
- Fixed Yet Another "object reference not set to an instance of an object" (Bug #5496 [http://bugs.mysql.com/5496])
- Fixed problem in PacketReader where it could try to allocate the wrong buffer size in EnsureCapacity
- Fixed GetBoolean returns wrong values (Bug #6227 [http://bugs.mysql.com/6227])
- Fixed IndexOutOfBounds when reading BLOB with DataReader with GetString(index) (Bug #6230 [http://bugs.mysql.com/6230])

26.2.5.8. Version 1.0.0 04-09-01

- Fixed BUG# 3889 Thai encoding not correctly supported
- Updated many of the test cases
- Fixed problem with using compression
- Bumped version number to 1.0.0 for beta 1 release

- Added COPYING.rtf file for use in installer
- Removed all of the XML comment warnings (I'll clean them up better later)
- Removed some last references to ByteFX

26.2.5.9. Version 0.9.0 04-08-30

- Added test fixture for prepared statements
- All type classes now implement a SerializeBinary method for sending their data to a PacketWriter
- Added PacketWriter class that will enable future low-memory large object handling
- Fixed many small bugs in running prepared statements and stored procedures
- Changed command so that an exception will not be throw in executing a stored procedure with parameters in old syntax mode
- SingleRow behavior now working right even with limit
- GetBytes now only works on binary columns
- Logger now truncates long sql commands so blob columns don't blow out our log
- host and database now have a default value of "" unless otherwise set
- FIXED BUG# 5214 Connection Timeout seems to be ignored
- Added test case for bug# 5051: GetSchema not working correctly
- Fixed problem where GetSchema would return false for IsUnique when the column is key
- MySqlDataReader GetXXX methods now using the field level MySqlValue object and not performing conversions
- FIXED BUG# 5097: DataReader returning NULL for time column
- Added test case for LOAD DATA LOCAL INFILE
- Added replacetext custom nant task
- Added CommandBuilderTest fixture
- Added Last One Wins feature to CommandBuilder
- Fixed persist security info case problem
- Fixed GetBool so that 1, true, "true", and "yes" all count as trueWL# 2024 Make parameter mark configurable
- Added the "old syntax" connection string parameter to allow use of @ parameter marker
- Fixed Bug #4658 [http://bugs.mysql.com/4658] MySqlCommandBuilder
- Fixed Bug #4864 [http://bugs.mysql.com/4864] ByteFX.MySqlClient caches passwords if 'Persist Security Info' is false
- Updated license banner in all source files to include FLOSS exception
- Added new .Types namespace and implementations for most current MySql types

- Added MySqlField41 as a subclass of MySqlField
- Changed many classes to now use the new .Types types
- Changed type enum int to Int32, short to Int16, and bigint to Int64
- Added dummy types UInt16, UInt32, and UInt64 to allow an unsigned parameter to be made
- Connections are now reset when they are pulled from the connection pool
- Refactored auth code in driver so it can be used for both auth and reset
- Added UserReset test in PoolingTests.cs
- Connections are now reset using COM_CHANGE_USER when pulled from the pool
- Implemented SingleResultSet behavior
- Implemented support of unicode
- Added char set mappings for utf-8 and ucs-2
- fixed Bug #4520 [http://bugs.mysql.com/4520] time fields overflow using bytefx .net mysql driver
- Modified time test in data type test fixture to check for time spans where hours > 24
- Fixed Bug #4505 [http://bugs.mysql.com/4505] Wrong string with backslash escaping in Byte-Fx.Data.MySqlClient.MySqlParameter
- Added code to Parameter test case TestQuoting to test for backslashes
- Fixed Bug #4486 [http://bugs.mysql.com/4486] mysqlcommandbuilder fails with multi-word column names
- Fixed bug in TokenizeSql where underscore would terminate character capture in parameter name
- Added test case for spaces in column names
- Fixed bug# 4324 - MySqlDataReader.GetBytes don't works correctly
- Added GetBytes() test case to DataReader test fixture
- Now reading all server variables in InternalConnection.Configure into Hashtable
- Now using string[] for index map in CharSetMap
- Added CRInSQL test case for carriage returns in SQL
- setting maxPacketSize to default value in Driver.ctor
- Fixed bug #4442 [http://bugs.mysql.com/4442] - Setting MySqlDbType on a parameter doesn't set generic type
- Removed obsolete data types Long and LongLong
- Fixed bug# 4071 - Overflow exception thrown when using "use pipe" on connection string
- Changed "use pipe" keyword to "pipe name" or just "pipe"
- Allow reading multiple resultsets from a single query
- Added flags attribute to ServerStatusFlags enum

- Changed name of ServerStatus enum to ServerStatusFlags
- Fixed BUG #4386 [http://bugs.mysql.com/4386] - Inserted data row doesn't update properly
- Fixed bug #4074 [http://bugs.mysql.com/4074] - Error processing show create table
- Change Packet.ReadLenInteger to ReadPackedLong and added packet.ReadPackedInteger that alwasy reads integers packed with 2,3,4
- Added syntax.cs test fixture to test various SQL syntax bugs
- Fixed bug# 4149 Improper handling of time values. Now time value of 00:00:00 is not treated as null.
- Moved all test suite files into TestSuite folder
- Fixed bug where null column would move the result packet pointer backward
- Added new nant build script
- Fixed BUG #3917 [http://bugs.mysql.com/3917] - clear tablename so it will be regen'ed properly during the next GenerateSchema.
- Fixed bug #3915 [http://bugs.mysql.com/3915] - GetValues was always returning zero and was also always trying to copy all fields rather than respecting the size of the array passed in.
- Implemented shared memory access protocol
- Implemented prepared statements for MySQL 4.1
- Implemented stored procedures for MySQL 5.0
- Renamed MySqlInternalConnection to InternalConnection
- SQL is now parsed as chars, fixes problems with other languages
- Added logging and allow batch connection string options
- Fixed bug #3888 [http://bugs.mysql.com/3888] - RowUpdating event not set when setting the DataAdapter property
- Fixed bug in char set mapping
- Implemented 4.1 authentication
- Improved open/auth code in driver
- Improved how connection bits are set during connection
- Database name is now passed to server during initial handshake
- Changed namespace for client to MySql.Data.MySqlClient
- Changed assembly name of client to MySql.Data.dll
- Changed license text in all source files to GPL
- Added the MySqlClient.build Nant file
- Removed the mono batch files
- Moved some of the unused files into notused folder so nant build file can use wildcards
- Implemented shared memory accesss

- Major revamp in code structure
- Prepared statements now working for MySql 4.1.1 and later
- Finished implementing auth for 4.0, 4.1.0, and 4.1.1
- Changed namespace from MySQL.Data.MySQLClient back to MySql.Data.MySqlClient
- Fixed bug in CharSetMapping where it was trying to use text names as ints
- Changed namespace to MySQL.Data.MySQLClient
- Integrated auth changes from UC2004
- Fixed bug where calling any of the GetXXX methods on a datareader before or after reading data would not throw the appropriate exception (thanks Luca Morelli <morelli.luca@iol.it>)
- Added TimeSpan code in parameter.cs to properly serialize a timespan object to mysql time format (thanks Gianluca Colombo <g.colombo@alfi.it>)
- Added TimeStamp to parameter serialization code. Prevented DataAdatper updates from working right (thanks MIchael King)
- Fixed a misspelling in MySqlHelper.cs (thanks Patrick Kristiansen)

26.2.5.10. Version 0.76

- Driver now using charset number given in handshake to create encoding
- Changed command editor to point to MySqlClient.Design
- Fixed bug in Version.isAtLeast
- Changed DBConnectionString to support changes done to MySqlConnectionString
- Removed SqlCommandEditor and DataAdapterPreviewDialog
- Using new long return values in many places
- Integrated new CompressedStream class
- Changed ConnectionString and added attributes to allow it to be used in MySqlClient.Design
- Changed packet.cs to support newer lengths in ReadLenInteger
- changed other classes to use new properties and fields of MySqlConnectionString
- ConnectionInternal is now using PING to see if the server is alive
- Moved toolbox bitmaps into resource/
- Changed field.cs to allow values to come directly from row buffer
- Changed to use the new driver.Send syntax
- Using a new packet queueing system
- started work handling the "broken" compression packet handling
- Fixed bug in StreamCreator where failure to connect to a host would continue to loop infinitly (thanks Kevin Casella)

- Improved connectstring handling
- Moved designers into Pro product
- Removed some old commented out code from command.cs
- Fixed a problem with compression
- Fixed connection object where an exception throw prior to the connection opening would not leave the connection in the connecting state (thanks Chris Cline)
- Added GUID support
- Fixed sequence out of order bug (thanks Mark Reay)

26.2.5.11. Version 0.75

- Enum values now supported as parameter values (thanks Philipp Sumi)
- Year datatype now supported
- fixed compression
- Fixed bug where a parameter with a TimeSpan as the value would not serialize properly
- Fixed bug where default ctor would not set default connection string values
- Added some XML comments to some members
- Work to fix/improve compression handling
- Improved ConnectionString handling so that it better matches the standard set by SqlClient.
- A MySqlException is now thrown if a username is not included in the connection string
- Localhost is now used as the default if not specified on the connection string
- An exception is now thrown if an attempt is made to set the connection string while the connection is open
- Small changes to ConnectionString docs
- Removed MultiHostStream and MySqlStream. Replaced it with Common/StreamCreator
- Added support for Use Pipe connection string value
- Added Platform class for easier access to platform utility functions
- Fixed small pooling bug where new connection was not getting created after IsAlive fails
- Added Platform.cs and StreamCreator.cs
- Fixed Field.cs to properly handle 4.1 style timestamps
- Changed Common.Version to Common.DBVersion to avoid name conflict
- Fixed field.cs so that text columns return the right field type (thanks beni27@gmx.net)
- Added MySqlError class to provide some reference for error codes (thanks Geert Veenstra)

26.2.5.12. Version 0.74

- Added Unix socket support (thanks Mohammad DAMT [md@mt.web.id])
- only calling Thread.Sleep when no data is available
- improved escaping of quote characters in parameter data
- removed misleading comments from parameter.cs
- fixed pooling bug
- same pooling bug fixed again!! ;-)
- Fixed ConnectionSTring editor dialog (thanks marco p (pomarc))
- UserId now supported in connection strings (thanks Jeff Neeley)
- Attempting to create a parameter that is not input throws an exception (thanks Ryan Gregg)
- Added much documentation
- checked in new MultiHostStream capability. Big thanks to Dan Guisinger for this. he originally submitted the code and idea of supporting multiple machines on the connect string.
- Added alot of documentation. Still alot to do.
- Fixed speed issue with 0.73
- changed to Thread.Sleep(0) in MySqlDataStream to help optimize the case where it doesn't need to wait (thanks Todd German)
- Prepopulating the idlepools to MinPoolSize
- Fixed MySqlPool deadlock condition as well as stupid bug where CreateNewPooledConnection was not ever adding new connections to the pool. Also fixed MySqlStream.ReadBytes and ReadByte to not use TicksPerSecond which does not appear to always be right. (thanks Matthew J. Peddlesden)
- Fix for precision and scale (thanks Matthew J. Peddlesden)
- Added Thread.Sleep(1) to stream reading methods to be more cpu friendly (thanks Sean McGinnis)
- Fixed problem where ExecuteReader would sometime return null (thanks Lloyd Dupont)
- Fixed major bug with null field handling (thanks Naucki)
- enclosed queries for max_allowed_packet and characterset inside try catch (and set defaults)
- fixed problem where socket was not getting closed properly (thanks Steve!)
- Fixed problem where ExecuteNonQuery was not always returning the right value
- Fixed InternalConnection to not use @@session.max_allowed_packet but use @@max_allowed_packet. (Thanks Miguel)
- Added many new XML doc lines
- Fixed sql parsing to not send empty queries (thanks Rory)
- Fixed problem where the reader was not unpeeking the packet on close
- Fixed problem where user variables were not being handled (thanks Sami Vaaraniemi)
- Fixed loop checking in the MySqlPool (thanks Steve M. Brown)

- Fixed ParameterCollection.Add method to match SqlClient (thanks Joshua Mouch)
- Fixed ConnectionSTring parsing to handle no and yes for boolean and not lowercase values (thanks Naucki)
- Added InternalConnection class, changes to pooling
- Implemented Persist Security Info
- Added security.cs and version.cs to project
- Fixed DateTime handling in Parameter.cs (thanks Burkhard Perkens-Golomb)
- Fixed parameter serialization where some types would throw a cast exception
- Fixed DataReader to convert all returned values to prevent casting errors (thanks Keith Murray)
- Added code to Command.ExecuteReader to return null if the initial SQL command throws an exception (thanks Burkhard Perkens-Golomb)
- Fixed ExecuteScalar bug introduced with restructure
- Restructure to allow for LOCAL DATA INFILE and better sequencing of packets
- Fixed several bugs related to restructure.
- Early work done to support more secure passwords in Mysql 4.1. Old passwords in 4.1 not supported yet
- Parameters appearing after system parameters are now handled correctly (Adam M. (adammil))
- strings can now be assigned directly to blob fields (Adam M.)
- Fixed float parameters (thanks Pent)
- Improved Parameter ctor and ParameterCollection.Add methods to better match SqlClient (thx Joshua Mouch)
- Corrected Connection.CreateCommand to return a MySqlCommand type
- Fixed connection string designer dialog box problem (thanks Abraham Guyt)
- Fixed problem with sending commands not always reading the response packet (thanks Joshua Mouch)
- Fixed parameter serialization where some blobs types were not being handled (thanks Sean McGinnis)
- Removed spurious MessageBox.show from DataReader code (thanks Joshua Mouch)
- Fixed a nasty bug in the split sql code (thanks everyone! :-))

26.2.5.13. Version 0.71

- Fixed bug in MySqlStream where too much data could attempt to be read (thanks Peter Belbin)
- Implemented HasRows (thanks Nash Pherson)
- Fixed bug where tables with more than 252 columns cause an exception (thanks Joshua Kessler)
- Fixed bug where SQL statements ending in ; would cause a problem (thanks Shane Krueger)

- Fixed bug in driver where error messages were getting truncated by 1 character (thanks Shane Krueger)
- Made MySqlException serializable (thanks Mathias Hasselmann)

26.2.5.14. Version 0.70

- Updated some of the character code pages to be more accurate
- Fixed problem where readers could be opened on connections that had readers open
- Release of 0.70
- Moved test to separate assembly MySqlClientTests
- Fixed stupid problem in driver with sequence out of order (Thanks Peter Belbin)
- Added some pipe tests
- Increased default max pool size to 50
- Compiles with Mono 0-24
- Fixed connection and data reader dispose problems
- Added String datatype handling to parameter serialization
- Fixed sequence problem in driver that occurred after thrown exception (thanks Burkhard Perkens-Golomb)
- Added support for CommandBehavior.SingleRow to DataReader
- Fixed command sql processing so quotes are better handled (thanks Theo Spears)
- Fixed parsing of double, single, and decimal values to account for non-English separators. You still have to use the right syntax if you using hard coded sql, but if you use parameters the code will convert floating point types to use '.' appropriately internal both into the server and out. [Thanks anonymous]
- Added MySqlStream class to simplify timeOuts and driver coding.
- Fixed DataReader so that it is closed properly when the associated connection is closed. [thanks smishra]
- Made client more SqlClient compliant so that DataReaders have to be closed before the connection can be used to run another command
- Improved DBNull.Value handling in the fields
- Added several unit tests
- Fixed MySqlException so that the base class is actually called :-o
- Improved driver coding
- Fixed bug where NextResult was returning false on the last resultset
- Added more tests for MySQL
- Improved casting problems by equating unsigned 32bit values to Int64 and usigned 16bit values to Int32, and so forth.

- Added new ctor for MySqlParameter for (name, type, size, srccol)
- Fixed bug in MySqlDataReader where it didn't check for null fieldlist before returning field count
- Started adding MySqlClient unit tests (added MySqlClient/Tests folder and some test cases)
- Fixed some things in Connection String handling
- Moved INIT_DB to MySqlPool. I may move it again, this is in preparation of the conference.
- Fixed bug inside CommandBuilder that prevented inserts from happening properly
- Reworked some of the internals so that all three execute methods of Command worked properly
- FIxed many small bugs found during benchmarking
- The first cut of CoonectionPooling is working. "min pool size" and "max pool size" are respected.
- Work to enable multiple resultsets to be returned
- Character sets are handled much more intelligently now. The driver queries MySQL at startup for the default character set. That character set is then used for conversions if that code page can be loaded. If not, then the default code page for the current OS is used.
- Added code to save the inferred type in the name,value ctor of Parameter
- Also, inferred type if value of null parameter is changed using Value property
- Converted all files to use proper Camel case. MySQL is now MySql in all files. PgSQL is now PgSql
- Added attribute to PgSql code to prevent designer from trying to show
- Added MySQLDbType property to Parameter object and added proper conversion code to convert from DbType to MySQLDbType)
- Removed unused ObjectToString method from MySQLParameter.cs
- Fixed Add(..) method in ParameterCollection so that it doesn't use Add(name, value) instead.
- Fixed IndexOf and Contains in ParameterCollection to be aware that parameter names are now stored without @
- Fixed Command.ConvertSQLToBytes so it only allows characters that can be in MySQL variable names
- Fixed DataReader and Field so that blob fields read their data from Field.cs and GetBytes works right
- Added simple query builder editor to CommandText property of MySQLCommand
- Fixed CommandBuilder and Parameter serialization to account for Parameters not storing @ in their names
- Removed MySQLFieldType enum from Field.cs. Now using MySQLDbType enum
- Added Designer attribute to several classes to prevent designer view when using VS.Net
- Fixed Initial catalog typo in ConnectionString designer
- Removed 3 parameter ctor for MySQLParameter that conflicted with (name, type, value)

- changed MySQLParameter so paramName is now stored without leading @ (this fixed null inserts when using designer)
- Changed TypeConverter for MySQLParameter to use the ctor with all properties

26.2.5.15. Version 0.68

- Fixed sequence issue in driver
- Added DbParametersEditor to make parameter editing more like SqlClient
- Fixed Command class so that parameters can be edited using the designer
- Update connection string designer to support Use Compression flag
- Fixed string encoding so that European characters like ä will work correctly
- Creating base classes to aid in building new data providers
- Added support for UID key in connection string
- Field, parameter, command now using DBNull.Value instead of null
- CommandBuilder using DBNull.Value
- CommandBuilder now builds insert command correctly when an auto_insert field is not present
- Field now uses typeof keyword to return System.Types (performance)

26.2.5.16. Version 0.65

- MySQLCommandBuilder now implemented
- Transaction support now implemented (not all table types support this)
- GetSchemaTable fixed to not use xsd (for Mono)
- Driver is now Mono-compatible!!
- TIME data type now supported
- More work to improve Timestamp data type handling
- Changed signatures of all classes to match corresponding SqlClient classes

26.2.5.17. Version 0.60

- Protocol compression using SharpZipLib (www.icsharpcode.net)
- Named pipes on Windows now working properly
- Work done to improve Timestamp data type handling
- Implemented IEnumerable on DataReader so DataGrid would work

26.2.5.18. Version 0.50

- Speed increased dramatically by removing bugging network sync code
- Driver no longer buffers rows of data (more ADO.Net compliant)
- Conversion bugs related to TIMESTAMP and DATETIME fields fixed

26.3. MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language via a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC-3.0 “Type 4” driver, which means that is pure Java, implements version 3.0 of the JDBC specification, and communicates directly with the MySQL server using the MySQL protocol.

This document is arranged for a beginning JDBC developer. If you are already experienced with using JDBC, you might consider starting with the section Section 26.3.2, “Installing Connector/J”.

Although JDBC is useful by itself, we would hope that if you are not familiar with JDBC that after reading the first few sections of this manual, that you would avoid using “naked” JDBC for all but the most trivial problems and consider using one of the popular persistence frameworks such as Hibernate [http://www.hibernate.org/], Spring's JDBC templates [http://www.springframework.org/] or Ibatis SQL Maps [http://www.ibatis.com/common/sqlmaps.html] to do the majority of repetitive work and heavier lifting that is sometimes required with JDBC.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- JDBC Basics [http://java.sun.com/docs/books/tutorial/jdbc/basics/index.html] — A tutorial from Sun covering beginner topics in JDBC
- JDBC Short Course [http://java.sun.com/developer/onlineTraining/Database/JDBCShortCourse/index.html] — A more in-depth tutorial from Sun and JGuru

26.3.1. Basic JDBC concepts

This section provides some general JDBC background.

26.3.1.1. Connecting to MySQL using the `DriverManager` Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

The `DriverManager` needs to be told which JDBC drivers it should try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
```

```
// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
            // broken Java implementations

            Class.forName("com.mysql.jdbc.Driver").newInstance();
        } catch (Exception ex) {
            // handle the error
        }
}
```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

Example 26.1. Obtaining a Connection From the `DriverManager`

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. You should see the API documentation that comes with your JDK for more specific information on how to use them.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

    ... try {
            Connection conn = DriverManager.getConnection("jdbc:mysql://localhos

            // Do something with the Connection

          ....
        } catch (SQLException ex) {
            // handle any errors
            System.out.println("SQLException: " + ex.getMessage());
            System.out.println("SQLState: " + ex.getSQLState());
            System.out.println("VendorError: " + ex.getErrorCode());
        }
```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

26.3.1.2. Using Statements to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved via one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows affected by the update statement.

If you don't know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE`/`INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

Example 26.2. Using java.sql.Statement to Execute a SELECT Query

```
// assume that conn is an already created JDBC connection
Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
} finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) { // ignore }

        rs = null;
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) { // ignore }

        stmt = null;
    }
}
```

26.3.1.3. Using `CallableStatements` to Execute Stored Procedures

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

MySQL's stored procedure syntax is documented in the "Stored Procedures and Functions [http://www.mysql.com/doc/en/stored-procedures.html]" section of the MySQL Reference Manual.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

The following example shows a stored procedure that returns the value of `inOutParam` incremen-

ted by 1, and the string passed in via `inputParam` as a `ResultSet`:

Example 26.3. Stored Procedure Example

```
CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), INOUT inOutParam INT)
BEGIN
    DECLARE z INT;
    SET z = inOutParam + 1;
    SET inOutParam = z;

    SELECT inputParam;

    SELECT CONCAT('zyxw', inputParam);
END
```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()` .

   Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

   ### Example 26.4. Using `Connection.prepareCall()`

   ```
   import java.sql.CallableStatement;

   ...

       //
       // Prepare a call to the stored procedure 'demoSp'
       // with two parameters
       //
       // Notice the use of JDBC-escape syntax ({call ...})
       //

       CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

       cStmt.setString(1, "abcdefg");
   ```

   ## Note

   `Connection.prepareCall()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, you should try to minimize unnecessary calls to `Connection.prepareCall()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

   To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

   ### Example 26.5. Registering Output Parameters

```
import java.sql.Types;
...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//

//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//

cStmt.registerOutParameter(2, Types.INTEGER);

//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//

cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...
```

3. Set the input parameters (if any exist)

   Input and in/out parameters are set as for `PreparedStatement` objects. However, `CallableStatement` also supports setting parameters by name:

Example 26.6. Setting `CallableStatement` Input Parameters

```
...

    //
    // Set a parameter by index
    //

    cStmt.setString(1, "abcdefg");

    //
    // Alternatively, set a parameter using
    // the parameter name
    //

    cStmt.setString("inputParameter", "abcdefg");

    //
    // Set the 'in/out' parameter using an index
    //

    cStmt.setInt(2, 1);

    //
    // Alternatively, set the 'in/out' parameter
```

```
        // by name
        //

        cStmt.setInt("inOutParam", 1);

    ...
```

4. Execute the `CallableStatement`, and retrieve any result sets or output parameters.

   Although `CallableStatement` supports calling any of the `Statement` execute methods (`executeUpdate()`, `executeQuery()` or `execute()`), the most flexible method to call is `execute()`, as you do not need to know ahead of time if the stored procedure returns result sets:

   Example 26.7. Retrieving Results and Output Parameter Values

```
    ...

        boolean hadResults = cStmt.execute();

        //
        // Process all returned result sets
        //

        while (hadResults) {
            ResultSet rs = cStmt.getResultSet();

            // process result set
            ...

            hadResults = cStmt.getMoreResults();
        }

        //
        // Retrieve output parameters
        //
        // Connector/J supports both index-based and
        // name-based retrieval
        //

        int outputValue = cStmt.getInt(2); // index-based

        outputValue = cStmt.getInt("inOutParam"); // name-based

    ...
```

26.3.1.4. Retrieving `AUTO_INCREMENT` Column Values

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported “auto increment” or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC-3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC-3.0. The second example shows how you can

retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

Example 26.8. Retrieving `AUTO_INCREMENT` Column Values using `Statement.getGeneratedKeys()`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets assuming you have a
    // Connection 'conn' to a MySQL database already
    // available

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
            "INSERT INTO autoIncTutorial (dataField) "
            + "values ('Can I Get the Auto Increment Field?')",
            Statement.RETURN_GENERATED_KEYS);

    //
    // Example of using Statement.getGeneratedKeys()
    // to retrieve the value of an auto-increment
    // value
    //

    int autoIncKeyFromApi = -1;

    rs = stmt.getGeneratedKeys();

    if (rs.next()) {
        autoIncKeyFromApi = rs.getInt(1);
    } else {

        // throw an exception from here
    }

    rs.close();

    rs = null;

    System.out.println("Key returned from getGeneratedKeys():"
        + autoIncKeyFromApi);
} finally {

    if (rs != null) {
```

```
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Example 26.9. Retrieving `AUTO_INCREMENT` Column Values using `SELECT LAST_INSERT_ID()`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

    stmt = conn.createStatement();

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
            "INSERT INTO autoIncTutorial (dataField) "
            + "values ('Can I Get the Auto Increment Field?')");

    //
    // Use the MySQL LAST_INSERT_ID()
    // function to do the same thing as getGeneratedKeys()
    //

    int autoIncKeyFromFunc = -1;
    rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

    if (rs.next()) {
        autoIncKeyFromFunc = rs.getInt(1);
    } else {
        // throw an exception from here
    }

    rs.close();
```

```
    System.out.println("Key returned from " + "'SELECT LAST_INSERT_ID()': "
        + autoIncKeyFromFunc);

} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Example 26.10. Retrieving `AUTO_INCREMENT` Column Values in `Updatable ResultSets`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'
    // one, assuming you have a Connection 'conn' to
    // a MySQL database already available
    //

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Example of retrieving an AUTO INCREMENT key
    // from an updatable result set
    //

    rs = stmt.executeQuery("SELECT priKey, dataField "
       + "FROM autoIncTutorial");

    rs.moveToInsertRow();

    rs.updateString("dataField", "AUTO INCREMENT here?");
    rs.insertRow();
```

```
    //
    // the driver adds rows at the end
    //

    rs.last();

    //
    // We should now be on the row we just inserted
    //

    int autoIncKeyFromRS = rs.getInt("priKey");

    rs.close();

    rs = null;

    System.out.println("Key returned for inserted row: "
        + autoIncKeyFromRS);

} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

When you run the preceding example code, you should get the following output: Key returned from `getGeneratedKeys()`: 1 Key returned from `SELECT LAST_INSERT_ID()`: 1 Key returned for inserted row: 2 You should be aware, that at times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value will be overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

26.3.2. Installing Connector/J

Use the following instructions to install Connector/J

26.3.2.1. Required Software Versions

26.3.2.1.1. Java Versions Supported

MySQL Connector/J supports Java-2 JVMs, including JDK-1.2.x, JDK-1.3.x, JDK-1.4.x and JDK-1.5.x, and requires JDK-1.4.x or newer to compile (but not run). MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on JDKs older than 1.4 unless the class verifier is turned off (`-Xverify:none`), as the class

verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

26.3.2.1.2. MySQL Server Version Guidelines

MySQL Connector/J supports all known MySQL server versions. Some features (foreign keys, updatable result sets) require more recent versions of MySQL to operate.

When connecting to MySQL server version 4.1 or newer, it is best to use MySQL Connector/J version 3.1, as it has full support for features in the newer versions of the server, including Unicode characters, views, stored procedures and server-side prepared statements.

Although Connector/J version 3.0 will connect to MySQL server, version 4.1 or newer, and implements Unicode characters and the new authorization mechanism, Connector/J 3.0 will not be updated to support new features in current and future server versions.

26.3.2.1.3. Installing the Driver and Configuring the `CLASSPATH`

MySQL Connector/J is distributed as a .zip or .tar.gz archive containing the sources, the class files a class-file only “binary” .jar archive named "`mysql-connector-java-[version]-bin.jar`", and starting with Connector/J 3.1.8 a “debug” build of the driver in a file named "`mysql-connector-java-[version]-bin-g.jar`".

Starting with Connector/J 3.1.9, we don't ship the .class files “unbundled”, they are only available in the JAR archives that ship with the driver.

You should not use the “debug” build of the driver unless instructed to do so when reporting a problem or bug to MySQL AB, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

You will need to use the appropriate graphical or command-line utility to un-archive the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long filenames in the distribution, we use the GNU tar archive format. You will need to use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

Once you have extracted the distribution archive, you can install the driver by placing mysql-connector-java-[version]-bin.jar in your classpath, either by adding the FULL path to it to your CLASSPATH environment variable, or by directly specifying it with the command line switch -cp when starting your JVM

If you are going to use the driver with the JDBC DriverManager, you would use "com.mysql.jdbc.Driver" as the class that implements java.sql.Driver.

Example 26.11. Setting the CLASSPATH Under UNIX

The following command works for 'csh' under UNIX:

```
$ setenv CLASSPATH /path/to/mysql-connector-java-[version]-bin.jar:$CLASSPATH
```

The above command can be added to the appropriate startup file for the login shell to make MySQL Connector/J available to all Java applications.

If you want to use MySQL Connector/J with an application server such as Tomcat or JBoss, you will have to read your vendor's documentation for more information on how to configure third-party

class libraries, as most application servers ignore the CLASSPATH environment variable. This document does contain configuration examples for some J2EE application servers in the section named "Using Connector/J with J2EE and Other Java Frameworks", however the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's .jar file in the WEB-INF/lib subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the MysqlDataSource or MysqlConnectionPoolDataSource classes in the com.mysql.jdbc.jdbc2.optional package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the javax.sql.XADataSource interface is implemented via the com.mysql.jdbc.jdbc2.optional.MysqlXADataSource class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various MysqlDataSource classes support the following parameters (through standard "set" mutators):

- user
- password
- serverName (see the previous section about fail-over hosts)
- databaseName
- port

26.3.2.2. Upgrading from an Older Version

MySQL AB tries to keep the upgrade process as easy as possible, however as is the case with any software, sometimes changes need to be made in new versions to support new features, improve existing functionality, or comply with new standards.

This section has information about what users who are upgrading from one version of Connector/J to another (or to a new version of the MySQL server, with respect to JDBC functionality) should be aware of.

26.3.2.2.1. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, SQLState codes returned in error messages by the server and various performance enhancements that can be enabled or disabled via configuration properties.

- Unicode Character Sets - See the next section, as well as the "Character Sets" section in the server manual for information on this new feature of MySQL. If you have something misconfigured, it will usually show up as an error with a message similar to 'Illegal mix of collations'.
- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

  Starting with version 3.1.7, the driver scans SQL you are preparing via all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing 'emulateUnsupportedPstmts=false' in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

- Datetimes with all-zero components ('0000-00-00 ...') - These values can not be represented reliably in Java. Connector/J 3.0.x always converted them to NULL when being read from a ResultSet.

  Connector/J 3.1 throws an exception by default when these values are encountered as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the ' zeroDateTimeBehavior ' configuration property. The allowable values are: 'exception' (the default), which throws an SQLException with an SQLState of 'S1009', 'convertToNull', which returns NULL instead of the date, and 'round', which rounds the date to the nearest closest value which is '0001-01-01'.

  Starting with Connector/J 3.1.7, ResultSet.getString() can be decoupled from this behavior via ' noDatetimeStringSync=true ' (the default value is 'false') so that you can get retrieve the unaltered all-zero value as a String. It should be noted that this also precludes using any timezone conversions, therefore the driver will not allow you to enable noDatetimeStringSync and useTimezone at the same time.

- New SQLState Codes - Connector/J 3.1 uses SQL:1999 SQLState codes returned by the MySQL server (if supported), which are different than the “legacy” X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return SQLStates as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the following configuration property:

  ```
  useSqlStateCodes=false
  ```

- Calling ResultSet.getString() on a BLOB column will now return the address of the byte[] array that represents it, instead of a String representation of the BLOB. BLOBs have no character set, so they can't be converted to java.lang.Strings without data loss or corruption.

  To store strings in MySQL with LOB behavior, use one of the TEXT types, which the driver will treat as a java.sql.Clob.

- Starting with Connector/J 3.1.8 a “debug” build of the driver in a file named "`mysql-connector-java-[version]-bin-g.jar`" is shipped alongside the normal “binary” jar file that is named "`mysql-connector-java-[version]-bin.jar`".

  Starting with Connector/J 3.1.9, we don't ship the .class files “unbundled”, they are only available in the JAR archives that ship with the driver.

  You should not use the “debug” build of the driver unless instructed to do so when reporting a problem or bug to MySQL AB, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the AspectJ runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

26.3.2.2.2. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in latin1 tables on the server.

  Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in

MySQL server version 4.1 or newer, you should add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

  ```
  useServerPrepStmts=false
  ```

26.3.3. JDBC Reference

26.3.3.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements java.sql.Driver in MySQL Connector/J is 'com.mysql.jdbc.Driver'. The 'org.gjt.mm.mysql.Driver' class name is also usable to remain backward-compatible with MM.MySQL. You should use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([,]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database][?propertyName1][=proper
```

If the hostname is not specified, it defaults to '127.0.0.1'. If the port is not specified, it defaults to '3306', the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database][?propertyName1][=propertyVal
```

If the database is not specified, the connection will be made with no default database. In this case, you will need to either call the `setCatalog()` method on the Connection instance or fully-specify table names using the database name (i.e. 'SELECT dbname.tablename.colname FROM dbname.tablename...') in your SQL. Not specifying the database to use upon connection is generally only useful when building tools that work with multiple databases, such as GUI database managers.

MySQL Connector/J has fail-over support. This allows the driver to fail-over to any number of “slave” hosts and still perform read-only queries. Fail-over only happens when the connection is in an autoCommit(true) state, because fail-over can not happen reliably when a transaction is in progress. Most application servers and connection pools set autoCommit to 'true' at the end of every transaction/connection use.

The fail-over functionality has the following behavior:

If the URL property "autoReconnect" is false: Failover only happens at connection initialization, and failback occurs when the driver determines that the first host has become available again.

If the URL property "autoReconnect" is true: Failover happens when the driver determines that the connection has failed (before *every* query), and falls back to the first host when it determines that the host has become available again (after queriesBeforeRetryMaster queries have been issued).

In either case, whenever you are connected to a "failed-over" server, the connection will be set to read-only state, so queries that would modify data will have exceptions thrown (the query will *never* be processed by the MySQL server).

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a DataSource object or for a Connection object.

Configuration Properties can be set in one of the following ways:

- Using the set*() methods on MySQL implementations of java.sql.DataSource (which is the preferred method when using implementations of java.sql.DataSource):
  - com.mysql.jdbc.jdbc2.optional.MysqlDataSource
  - com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource
- As a key/value pair in the java.util.Properties instance passed to DriverManager.getConnection() or Driver.connect()
- As a JDBC URL parameter in the URL given to java.sql.DriverManager.getConnection(), java.sql.Driver.connect() or the MySQL implementations of javax.sql.DataSource's setURL() method.

Note

If the mechanism you use to configure a JDBC URL is XML-based, you will need to use the XML character literal & to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following table:

Table 26.1. Connection Properties

Property Name	Definition	Required?	Default Value	Since Version
Connection/Authentication				
user	The user to connect as	No		all
password	The password to use when connecting	No		all
socketFactory	The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.	No	com.mysql.jdbc.StandardSocketFactory	3.0.3
connectTimeout	Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.	No	0	3.0.1
socketTimeout	Timeout on network socket oper-	No	0	3.0.1

Property Name	Definition	Required?	Default Value	Since Version
	ations (0, the default means no timeout).			
useConfigs	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.	No		3.1.5
interactiveClient	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	No	false	3.1.0
propertiesTransform	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection	No		3.1.4
useCompression	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	No	false	3.0.17
High Availability and Clustering				
autoReconnect	Should the driver try to re-establish stale or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued	No	false	1.1

Property Name	Definition	Required?	Default Value	Since Version
	on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don'thandle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead andstale connections properly. Alternatively, investigate setting the MySQL server variable "wait_timeout"to some high value rather than the default of 8 hours.			
autoReconnect-ForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	No	false	3.1.3
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	No	true	3.0.12
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnectionsat the end of every transaction?	No	false	3.0.10
roundRobinLoad-Balance	When autoReconnect is enabled, and failover-Readonly is false, should we pick hosts to connect to on a round-robin basis?	No	false	3.1.2
queriesBe-foreRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host fail-	No	50	3.0.2

Property Name	Definition	Required?	Default Value	Since Version
	over). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.			
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting to reconnect to the master server? Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Time in seconds, defaults to 30	No	30	3.0.2
enableDeprecatedAutoreconnect	Auto-reconnect functionality is deprecated starting with version 3.2, and will be removed in version 3.3. Set this property to 'true' to disable the check for the feature being configured.	No	false	3.2.1
Security				
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one statement (true/false, defaults to 'false'	No	false	3.1.1
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	No	false	3.0.2
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	No	false	3.1.0
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA	No	false	3.1.4

Property Name	Definition	Required?	Default Value	Since Version
	LOCAL INFILE' statements?			
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	No	false	3.0.1
Performance Extensions				
metadataCacheSize	The number of queries to cacheResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	No	50	3.1.1
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	No	25	3.0.10
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?	No	256	3.0.10
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?	No	false	5.0.0
blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements	No	1048576	3.1.9
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	No	false	3.1.2
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the “check” for suitability of server-side	No	false	3.0.10

Property Name	Definition	Required?	Default Value	Since Version
	prepared and server-side prepared statements themselves?			
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	No	false	3.1.1
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	No	false	3.1.5
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	No	0	3.1.9
dontTrackOpenResources	The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.	No	false	3.1.7
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/session?	No	false	3.1.5
elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state	No	false	3.1.3

Property Name	Definition	Required?	Default Value	Since Version
	doesn't match the requested state by Connection.setAutoCommit(boolean)?			
holdResultsOpenOverStatementClose	Should the driver close result sets on Statement.close() as required by the JDBC specification?	No	false	3.1.7
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	No	1048576	3.2.1
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	No	true	3.1.4
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation(), rather than querying the database?	No	false	3.1.7
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	No	true	3.1.5
Debuging/Profiling				
logger	The name of a class that implements 'com.mysql.jdbc.log.Log' that will be used to log messages to.(default is 'com.mysql.jdbc.log.StandardLogger', which logs to STDERR)	No	com.mysql.jdbc.log.StandardLogger	3.1.1
profileSQL	Trace queries and their execution/	No	false	3.1.0

Property Name	Definition	Required?	Default Value	Since Version
	fetch times to the configured logger (true/false) defaults to 'false'			
reportMetricsIntervalMillis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	No	30000	3.1.2
maxQuerySizeToLog	Controls the maximum length/size of a query that will get logged when profiling or tracing	No	2048	3.1.3
packetDebugBufferSize	The maximum number of packets to retain when 'enablePacketDebug' is true	No	20	3.1.3
slowQueryThresholdMillis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	No	2000	3.1.2
useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	No	false	3.1.1
autoGenerateTestcaseScript	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	No	false	3.1.9
dumpMetadataOnColumnNotFound	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	No	false	3.1.13
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	No	false	3.1.3
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBuf-	No	false	3.1.3

Property Name	Definition	Required?	Default Value	Since Version
	ferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code			
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	No	false	3.1.2
logSlowQueries	Should queries that take longer than 'slowQueryThresholdMillis' be logged?	No	false	3.1.2
traceProtocol	Should trace-level network protocol be logged?	No	false	3.1.2
Miscellaneous				
useUnicode	Should the driver use Unicode character encodings when handling strings? Should only be used when the driver can't determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true'	No	true	1.1g
characterEncoding	If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect')	No		1.1g
characterSetResults	Character set to tell the server to return results as.	No		3.0.13
connectionCollation	If set, tells the server to use this collation via 'set	No		3.0.13

Property Name	Definition	Required?	Default Value	Since Version
	colla-tion_connection'			
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.	No		3.1.8
allowNanAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	No	false	3.1.5
autoClosePStmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	No	false	3.1.12
autoDeserialize	Should the driver automatically detect and deserialize objects stored in BLOB fields?	No	false	3.1.5
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	No	false	2.0.7
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding	No		5.0.0
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	No	false	3.0.9

Property Name	Definition	Required?	Default Value	Since Version
continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	No	true	3.0.3
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	No	false	3.1.9
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	No	true	3.1.8
emulateLocators	N/A	No	false	3.1.0
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?	No	true	3.1.7
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	No	false	3.0.9
jdbcCompliantTruncation	Should the driver throw java.sql.DataTruncation exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings(MySQL 4.1.0 and newer)?	No	true	3.1.2
maxRows	The maximum number of rows to return (0, the default means return all rows).	No	-1	all versions
noDatetimeStringSync	Don't ensure that ResultSet.getDatetimeType().toString().equals(ResultSet.getSt	No	false	3.1.7

Property Name	Definition	Required?	Default Value	Since Version
	ring())			
noTimezoneConversionForTimeType	Don't convert TIME values using the server timezone if 'useTimezone'='true'	No	false	5.0.0
nullCatalogMeansCurrent	When DatabaseMetadataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)	No	true	3.1.8
nullNamePatternMatchesAll	Should DatabaseMetaData methods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)	No	true	3.1.8
overrideSupportsIntegrityEnhancementFacility	Should the driver return "true" for DatabaseMetaData.supportsIntegrityEnhancementFacility() even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)?	No	false	3.1.12
pedantic	Follow the JDBC spec to the letter.	No	false	3.0.0
processEs-	Should the driver	No	true	3.1.12

Property Name	Definition	Required?	Default Value	Since Version
capeCodesFor-PrepStmts	process escape codes in queries that are prepared?			
relaxAutoCommit	If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false, defaults to 'false')?	No	false	2.0.13
retainStatementAfterResultSetClose	Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.	No	false	3.1.11
rollbackOnPooledClose	Should the driver issue a rollback() when the logical connection in a pool is closed?	No	true	3.0.15
runningCTS13	Enables workarounds for bugs in Sun's JDBC compliance testsuite version 1.3	No	false	3.1.7
serverTimezone	Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone	No		3.0.2
strictFloatingPoint	Used only in older versions of compliance test	No	false	3.0.0
strictUpdates	Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?	No	true	3.0.4
tinyInt1isBit	Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?	No	true	3.0.16

Property Name	Definition	Required?	Default Value	Since Version
transformedBitIsBoolean	If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?	No	false	3.1.9
ultraDevHack	Create PreparedStatements for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')	No	false	2.0.3
useGmtMillisForDatetimes	Convert between session timezone and GMT before creating Date and Timestamp instances (value of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior.	No	false	3.1.12
useHostsInPrivileges	Add '@hostname' to users in DatabaseMetaData.getColumn/ TablePrivileges() (true/false), defaults to 'true'.	No	true	3.0.2
useInformationSchema	When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?	No	false	5.0.0
useJDBCCompliantTimezoneShift	Should the driver use JDBC-compliant rules when converting TIME/ TIMESTAMP/ DATETIME values' timezone information for those JDBC arguments which take	No	false	5.0.0

Property Name	Definition	Required?	Default Value	Since Version
	a java.util.Calendar argument? (Notice that this option is exclusive of the "use-Timezone=true" configuration option.)			
useOldUTF8Behavior	Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers	No	false	3.1.6
useOnlyServerErrorMessages	Don't prepend 'standard' SQLState error messages to error messages returned by the server.	No	true	3.0.15
useServerPrepStmts	Use server-side prepared statements if the server supports them? (defaults to 'true').	No	true	3.1.0
useSqlStateCodes	Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'	No	true	3.1.3
useStreamLengthsInPrepStmts	Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?	No	true	3.0.2
useTimezone	Convert time/date types between client and server timezones (true/false, defaults to 'false')?	No	false	3.0.2
useUnbufferedInput	Don't use BufferedInputStream for reading data from the server	No	true	3.0.11
yearIsDateType	Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?	No	true	3.1.9
zeroDateTimeBehavior	What should happen when the driver encounters	No	exception	3.1.4

Property Name	Definition	Required?	Default Value	Since Version
	DATETIME values that are composed entirely of zeroes (used by MySQL to represent invalid dates)? Valid values are 'exception', 'round' and 'convertToNull'.			

Connector/J also supports access to MySQL via named pipes on Windows NT/2000/XP using the 'NamedPipeSocketFactory' as a plugin-socket factory via the 'socketFactory' property. If you don't use a 'namedPipePath' property, the default of '\\.\pipe\MySQL' will be used. If you use the NamedPipeSocketFactory, the hostname and port number values in the JDBC url will be ignored.

Adding the following property to your URL will enable the NamedPipeSocketFactory:

socketFactory=com.mysql.jdbc.NamedPipeSocketFactory

Named pipes only work when connecting to a MySQL server on the same physical machine as the one the JDBC driver is being used on. In simple performance tests, it appears that named pipe access is between 30%-50% faster than the standard TCP/IP access.

You can create your own socket factories by following the example code in `com.mysql.jdbc.NamedPipeSocketFactory`, or `com.mysql.jdbc.StandardSocketFactory`.

26.3.3.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly-available version of Sun's JDBC compliance test suite. However, in many places the JDBC specification is vague about how certain functionality should be implemented, or the specification allows leeway in implementation.

This section gives details on a interface-by-interface level about how certain implementation decisions may affect how you use MySQL Connector/J.

- Blob

  The Blob implementation does not allow in-place modification (they are 'copies', as reported by the DatabaseMetaData.locatorsUpdateCopies() method). Because of this, you should use the corresponding PreparedStatement.setBlob() or ResultSet.updateBlob() (in the case of updatable result sets) methods to save changes back to the database.

  Starting with Connector/J version 3.1.0, you can emulate Blobs with locators by adding the property 'emulateLocators=true' to your JDBC URL. You must then use a column alias with the value of the column set to the actual name of the Blob column in the SELECT that you write to retrieve the Blob. The SELECT must also reference only one table, the table must have a primary key, and the SELECT must cover all columns that make up the primary key. The driver will then delay loading the actual Blob data until you retrieve the Blob and call retrieval methods (getInputStream(), getBytes(), and so forth) on it.

- CallableStatement

  Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer via the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- Clob

The Clob implementation does not allow in-place modification (they are 'copies', as reported by the DatabaseMetaData.locatorsUpdateCopies() method). Because of this, you should use the PreparedStatement.setClob() method to save changes back to the database. The JDBC API does not have a ResultSet.updateClob() method.

- Connection

  Unlike older versions of MM.MySQL the `isClosed()` method does not “ping” the server to determine if it is alive. In accordance with the JDBC specification, it only returns true if 'closed()' has been called on the connection. If you need to determine if the connection is still valid, you should issue a simple query, such as "SELECT 1". The driver will throw an exception if the connection is no longer valid.

- DatabaseMetaData

  Foreign Key information (getImported/ExportedKeys() and getCrossReference()) is only available from 'InnoDB'-type tables. However, the driver uses 'SHOW CREATE TABLE' to retrieve this information, so when other storage engines support foreign keys, the driver will transparently support them as well.

- Driver

- PreparedStatement

  PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement getParameterMetaData() or getMetaData() as it would require the driver to have a complete SQL parser in the client.

  Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and 'binary-encoded' result sets are used when the server supports them.

  Take care when using a server-side prepared statement with “large” parameters that are set via setBinaryStream(), setAsciiStream(), setUnicodeStream(), setBlob(), or setClob(). If you want to re-execute the statement with any “large” parameter changed to a non-“large” parameter, it is necessary to call clearParameters() and set all parameters again. The reason for this is as follows:

  - The driver streams the 'large' data 'out-of-band' to the prepared statement on the server side when the parameter is set (before execution of the prepared statement).

  - Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and can't be read from again.

  - If a parameter changes from “large” to non-“large”, the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior “large” value. This removes all of the 'large' data that has already been sent to the server, thus requiring the data to be re-sent, via the setBinaryStream(), setAsciiStream(), setUnicodeStream(), setBlob() or setClob() methods.

  Consequently, if you want to change the “type” of a parameter to a non-“large” one, you must call clearParameters() and set all parameters of the prepared statement again before it can be re-executed.

- ResultSet

  By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and can not allocate heap space in your JVM for the memory required, you can tell the driver to 'stream' the results back one row at a time.

  To enable this functionality, you need to create a Statement instance in the following manner:

  ```
  stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
  ```

```
                java.sql.ResultSet.CONCUR_READ_ONLY);
stmt.setFetchSize(Integer.MIN_VALUE);
```

The combination of a forward-only, read-only result set, with a fetch size of Integer.MIN_VALUE serves as a signal to the driver to “stream” result sets row-by-row. After this any result sets created with the statement will be retrieved row-by-row.

There are some caveats with this approach. You will have to read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using “streaming” results, you should process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- ResultSetMetaData

  The "isAutoIncrement()" method only works when using MySQL servers 4.0 and newer.

- Statement

  When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the "setFetchSize()" method has no effect, other than to toggle result set streaming as described above.

  MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so "setCursorName()" has no effect.

26.3.3.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a java.lang.String, and any numerical type can be converted to any of the Java numerical types, although round-off, overflow, or loss of precision may occur.

Starting with Connector/J 3.1.0, the JDBC driver will issue warnings or throw DataTruncation exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property "jdbcCompliantTruncation" and setting it to "false".

The conversions that are always guaranteed to work are listed in the following table:

Table 26.2. Conversion Table

These MySQL Data Types	Can always be converted to these Java types
CHAR, VARCHAR, BLOB, TEXT, ENUM, and SET	`java.lang.String`, `java.io.InputStream`, `java.io.Reader`, `java.sql.Blob`, `java.sql.Clob`

These MySQL Data Types	Can always be converted to these Java types
FLOAT, REAL, DOUBLE PRECISION, NUMERIC, DECIMAL, TINYINT, SMALLINT, MEDIUMINT, INTEGER, BIGINT	`java.lang.String`, `java.lang.Short`, `java.lang.Integer`, `java.lang.Long`, `java.lang.Double`, `java.math.BigDecimal` **Note** round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.
DATE, TIME, DATETIME, TIMESTAMP	`java.lang.String`, `java.sql.Date`, `java.sql.Timestamp`

The `ResultSet.getObject()` method uses the following type conversions between MySQL and Java types, following the JDBC specification where appropriate:

Table 26.3. MySQL Types to Java Types for ResultSet.getObject()

MySQL Type Name	Returned as Java Class
BIT(1) (new in MySQL-5.0)	`java.lang.Boolean`
BIT(> 1) (new in MySQL-5.0)	`byte[]`
TINYINT	`java.lang.Boolean` if the configuration property "tinyInt1isBit" is set to "true" (the default) and the storage size is "1", or `java.lang.Integer` if not.
BOOL , BOOLEAN	See TINYINT, above as these are aliases for TINYINT(1), currently.
SMALLINT[(M)] [UNSIGNED]	`java.lang.Integer` (regardless if UNSIGNED or not)
MEDIUMINT[(M)] [UNSIGNED]	`java.lang.Integer`, if UNSIGNED `java.lang.Long`
INT,INTEGER[(M)] [UNSIGNED]	`java.lang.Integer`, if UNSIGNED `java.lang.Long`
BIGINT[(M)] [UNSIGNED]	`java.lang.Long`, if UNSIGNED `java.math.BigInteger`
FLOAT[(M,D)]	`java.lang.Float`
DOUBLE[(M,B)]	`java.lang.Double`
DECIMAL[(M[,D])]	`java.math.BigDecimal`
DATE	`java.sql.Date`
DATETIME	`java.sql.Timestamp`
TIMESTAMP[(M)]	`java.sql.Timestamp`
TIME	`java.sql.Time`
YEAR[(2|4)]	`java.sql.Date` (with the date set two January 1st, at midnight)
CHAR(M)	`java.lang.String` (unless the character set for the column is BINARY, then `byte[]` is returned.

MySQL Type Name	Returned as Java Class
VARCHAR(M) [BINARY]	`java.lang.String` (unless the character set for the column is BINARY, then `byte[]` is returned.
BINARY(M)	`byte[]`
VARBINARY(M)	`byte[]`
TINYBLOB	`byte[]`
TINYTEXT	`java.lang.String`
BLOB	`byte[]`
TEXT	`java.lang.String`
MEDIUMBLOB	`byte[]`
MEDIUMTEXT	`java.lang.String`
LONGBLOB	`byte[]`
LONGTEXT	`java.lang.String`
ENUM('value1','value2',...)	`java.lang.String`
SET('value1','value2',...)	`java.lang.String`

26.3.3.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent via `Statement.execute()`, `Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the *`"useUnicode"`* and " *`characterEncoding`* " properties.

Starting with MySQL Server 4.1, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSets`.

The character encoding between client and server is automatically detected upon connection. The encoding used by the driver is specified on the server via the configuration variable ' *`character_set`* ' for server versions older than 4.1.0 and ' *`character_set_server`* ' for server versions 4.1.0 and newer. See the "Server Character Set and Collation [http://www.mysql.com/doc/en/Charset-server.html]" section in the MySQL server manual for more information.

To override the automatically-detected encoding on the client side, use the *`characterEncoding`* property in the URL used to connect to the server.

When specifying character encodings on the client side, Java-style names should be used. The following table lists Java-style names for MySQL character sets:

Table 26.4. MySQL to Java Encoding Name Translations

MySQL Character Set Name	Java-Style Character Encoding Name
usa7	US-ASCII
big5	Big5
gbk	GBK
sjis	SJIS (or Cp932 or MS932 for MySQL Server <

MySQL Character Set Name	Java-Style Character Encoding Name
	4.1.11)
cp932	Cp932 or MS932 (MySQL Server > 4.1.11)
gb2312	EUC_CN
ujis	EUC_JP
euc_kr	EUC_KR
latin1	ISO8859_1
latin1_de	ISO8859_1
german1	ISO8859_1
danish	ISO8859_1
latin2	ISO8859_2
czech	ISO8859_2
hungarian	ISO8859_2
croat	ISO8859_2
greek	ISO8859_7
hebrew	ISO8859_8
latin5	ISO8859_9
latvian	ISO8859_13
latvian1	ISO8859_13
estonia	ISO8859_13
dos	Cp437
pclatin2	Cp852
cp866	Cp866
koi8_ru	KOI8_R
tis620	TIS620
win1250	Cp1250
win1250ch	Cp1250
win1251	Cp1251
cp1251	Cp1251
win1251ukr	Cp1251
cp1257	Cp1257
macroman	MacRoman
macce	MacCentralEurope
utf8	UTF-8
ucs2	UnicodeBig

Warning

Do not issue the query 'set names' with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

To allow multiple character sets to be sent from the client, the "UTF-8" encoding should be used, either by configuring "utf8" as the default server character set, or by configuring the JDBC driver to use "UTF-8" through the `characterEncoding` property.

26.3.3.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL Support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: http://developer.java.sun.com/developer/bugParade/bugs/4273544.html
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL-4.0.4 or later, see: http://www.mysql.com/doc/en/Secure_connections.html
- A client certificate (covered later in this section)

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the 'SSL' subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server.

To use Java's 'keytool' to create a truststore in the current directory , and import the server's CA certificate ('cacert.pem'), you can do the following (assuming that'keytool' is in your path. It's located in the 'bin' subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert -file cacert.pem -keystore trus
```

Keytool will respond with the following information:

```
Enter keystore password:  *********
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus, O=MySQL AB, L=Orenburg, ST=S
-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus, O=MySQL AB, L=Orenburg, ST=
e-State, C=RU
Serial number: 0
Valid from: Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
         MD5:  61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
         SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]:  yes
Certificate was added to keystore
```

You will then need to generate a client certificate, so that the MySQL server knows that it is talking to a secure client:

```
 shell> keytool -genkey -keyalg rsa -alias mysqlClientCertificate -keystore key
```

Keytool will prompt you for the following information, and create a keystore named 'keystore' in the current directory.

You should respond with information that is appropriate for your situation:

```
Enter keystore password:  *********
What is your first and last name?
  [Unknown]:  Matthews
What is the name of your organizational unit?
  [Unknown]:  Software Development
What is the name of your organization?
  [Unknown]:  MySQL AB
What is the name of your City or Locality?
  [Unknown]:  Flossmoor
What is the name of your State or Province?
```

```
  [Unknown]:  IL
What is the two-letter country code for this unit?
  [Unknown]:  US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
 L=Flossmoor, ST=IL, C=US> correct?
  [no]:  y

Enter key password for <mysqlClientCertificate>
        (RETURN if same as keystore password):
```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing 'path_to_keystore_file' with the full path to the keystore file you created, 'path_to_truststore_file' with the path to the truststore file you created, and using the appropriate password values for each property.

```
-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=*********
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=*********
```

You will also need to set 'useSSL' to 'true' in your connection parameters for MySQL Connector/J, either by adding 'useSSL=true' to your URL, or by setting the property 'useSSL' to 'true' in the java.util.Properties instance you pass to DriverManager.getConnection().

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```
...
*** ClientHello, v3.1
RandomCookie:  GMT: 1018531834 bytes = { 199, 148, 180, 215, 74, 12, 54, 244,

...
```

JSSE provides debugging (to STDOUT) when you set the following system property: -Djavax.net.debug=all This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

26.3.3.6. Using Master/Slave Replication with ReplicationConnec-

tion

Starting with Connector/J 3.1.7, we've made available a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()` .

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this "replication-aware" connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is “sticky” to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is "time-sensitive" (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the “master” MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the " `com.mysql.jdbc.ReplicationDriver` " class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager` -based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager` .

Here is a short, simple example of how ReplicationDriver might be used in a standalone application.

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

    public static void main(String[] args) throws Exception {
        ReplicationDriver driver = new ReplicationDriver();

        Properties props = new Properties();

        // We want this for failover on the slaves
        props.put("autoReconnect", "true");

        // We want to load balance between the slaves
        props.put("roundRobinLoadBalance", "true");

        props.put("user", "foo");
        props.put("password", "bar");

        //
        // Looks like a normal MySQL JDBC url, with a comma-separated list
        // of hosts, the first being the 'master', the rest being any number
        // of slaves that the driver will load balance against
        //

        Connection conn =
            driver.connect("jdbc:mysql://master,slave1,slave2,slave3/test",
                props);

        //
        // Perform read/write work on the master
        // by setting the read-only flag to "false"
        //

        conn.setReadOnly(false);
        conn.setAutoCommit(false);
        conn.createStatement().executeUpdate("UPDATE some_table ....");
        conn.commit();
```

```
            //
            // Now, do a query from a slave, the driver automatically picks one
            // from the list
            //

            conn.setReadOnly(true);

            ResultSet rs = conn.createStatement().executeQuery("SELECT a,b,c FROM s

             .......
        }
}
```

26.3.4. Using Connector/J with J2EE and Other Java Frameworks

This section describes how to use Connector/J in several contexts.

26.3.4.1. General J2EE Concepts

This section provides general background on J2EE concepts that pertain to use of Connector/J.

26.3.4.1.1. Understanding Connection Pooling

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any thread that needs them.

This technique of “pooling” connections is based on the fact that most applications only need a thread to have access to a JDBC connection when they are actively processing a transaction, which usually take only milliseconds to complete. When not processing a transaction, the connection would otherwise sit idle. Instead, connection pooling allows the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it may be used by any other threads that want to use it.

When the connection is "loaned out" from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called DriverManager.getConnection() every time it needed a JDBC connection, however with connection pooling, your thread may end up using either a new, or already-existing connection.

Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage. The main benefits to connection pooling are:

- Reduced connection creation time

  Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are "recycled."

- Simplified programming model

  When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straight-forward JDBC programming techniques.

- Controlled resource usage

  If you don't use connection pooling, and instead create a new connection every time a thread needs one, your application's resource usage can be quite wasteful and lead to unpredictable be-

havior under load.

Remember that each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work!

Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

Luckily, Sun has standardized the concept of connection pooling in JDBC through the JDBC-2.0 "Optional" interfaces, and all major application servers have implementations of these APIs that work fine with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it via the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

Example 26.12. Using a Connection Pool with a J2EE Application Server

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         *  lookup  the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

         /*
          * Lookup the DataSource, which will be backed by a pool
          * that the application server provides. DataSource instances
          * are also a good candidate for caching as an instance
          * variable, as JNDI lookups can be expensive as well.
          */

        DataSource ds = (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

        /*
         * The following code is what would actually be in your
         * Servlet, JSP or EJB 'service' method...where you need
         * to work with a JDBC connection.
         */
```

```
        Connection conn = null;
        Statement stmt = null;

        try {
            conn = ds.getConnection();

            /*
             * Now, use normal JDBC programming to work with
             * MySQL, making sure to close each resource when you're
             * finished with it, which allows the connection pool
             * resources to be recovered as quickly as possible
             */

            stmt = conn.createStatement();
            stmt.execute("SOME SQL QUERY");

            stmt.close();
            stmt = null;

            conn.close();
            conn = null;
        } finally {
            /*
             * close any jdbc instances here that weren't
             * explicitly closed during normal code path, so
             * that we don't 'leak' resources...
             */

            if (stmt != null) {
                try {
                    stmt.close();
                } catch (sqlexception sqlex) {
                    // ignore -- as we can't do anything about it here
                }

                stmt = null;
            }

            if (conn != null) {
                try {
                    conn.close();
                } catch (sqlexception sqlex) {
                    // ignore -- as we can't do anything about it here
                }

                conn = null;
            }
        }
    }
}
```

As shown in the example above, after obtaining the JNDI InitialContext, and looking up the DataSource, the rest of the code should look familiar to anyone who has done JDBC programming in the past.

The most important thing to remember when using connection pooling is to make sure that no matter what happens in your code (exceptions, flow-of-control, and so forth), connections, and anything created by them (such as statements or result sets) are closed, so that they may be re-used, otherwise they will be "stranded," which in the best case means that the MySQL server resources they represent (such as buffers, locks, or sockets) may be tied up for some time, or worst case, may be tied up forever.

What's the Best Size for my Connection Pool?

As with all other configuration rules-of-thumb, the answer is "It depends." Although the optimal size depends on anticipated load and average database transaction time, the optimum connection

pool size is smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with response times that are acceptable.

To correctly size a connection pool for your application, you should create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be "unbounded," run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

26.3.4.2. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at http://jakarta.apache.org/tomcat/tomcat-5.0-doc/jndi-datasource-examples-howto.html which is current at the time this document was written.

First, install the .jar file that comes with Connector/J in `$CATALINA_HOME/common/lib` so that it is available to all applications installed in the container.

Next, Configure the JNDI DataSource by adding a declaration resource to `$CATALINA_HOME/conf/server.xml` in the context that defines your web application:

```
<Context ....>

  ...

  <Resource name="jdbc/MySQLDB"
              auth="Container"
              type="javax.sql.DataSource"/>

  <!-- The name you used above, must match _exactly_ here!

       The connection pool will be bound into JNDI with the name
       "java:/comp/env/jdbc/MySQLDB"
  -->

  <ResourceParams name="jdbc/MySQLDB">
    <parameter>
      <name>factory</name>
      <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
    </parameter>

    <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->

    <parameter>
      <name>maxActive</name>
      <value>10</value>
    </parameter>

    <!-- You don't want to many idle connections hanging around
         if you can avoid it, only enough to soak up a spike in
         the load -->

    <parameter>
      <name>maxIdle</name>
      <value>5</value>
    </parameter>

    <!-- Don't use autoReconnect=true, it's going away eventually
         and it's a crutch for older connection pools that couldn't
         test connections. You need to decide if your application is
         supposed to deal with SQLExceptions (hint, it should), and
```

```
      how much of a performance penalty you're willing to pay
      to ensure 'freshness' of the connection -->

  <parameter>
    <name>validationQuery</name>
    <value>SELECT 1</value>
  </parameter>

<!-- The most conservative approach is to test connections
     before they're given to your application. For most applications
     this is okay, the query used above is very small and takes
     no real server resources to process, other than the time used
     to traverse the network.

     If you have a high-load application you'll need to rely on
     something else. -->

  <parameter>
    <name>testOnBorrow</name>
    <value>true</value>
  </parameter>

<!-- Otherwise, or in addition to testOnBorrow, you can test
     while connections are sitting idle -->

  <parameter>
    <name>testWhileIdle</name>
    <value>true</value>
  </parameter>

  <!-- You have to set this value, otherwise even though
       you've asked connections to be tested while idle,
       the idle evicter thread will never run -->

  <parameter>
    <name>timeBetweenEvictionRunsMillis</name>
    <value>10000</value>
  </parameter>

  <!-- Don't allow connections to hang out idle too long,
       never longer than what wait_timeout is set to on the
       server...A few minutes or even fraction of a minute
       is sometimes okay here, it depends on your application
       and how much spikey load it will see -->

  <parameter>
    <name>minEvictableIdleTimeMillis</name>
    <value>60000</value>
  </parameter>

  <!-- Username and password used when connecting to MySQL -->

  <parameter>
   <name>username</name>
   <value>someuser</value>
  </parameter>

  <parameter>
   <name>password</name>
   <value>somepass</value>
  </parameter>

  <!-- Class name for the Connector/J driver -->

  <parameter>
     <name>driverClassName</name>
     <value>com.mysql.jdbc.Driver</value>
  </parameter>
```

```
    <!-- The JDBC connection url for connecting to MySQL, notice
         that if you want to pass any other MySQL-specific parameters
         you should pass them here in the URL, setting them using the
         parameter tags above will have no effect, you will also
         need to use &amp;amp; to separate parameter values as the
         ampersand is a reserved character in XML -->

    <parameter>
      <name>url</name>
      <value>jdbc:mysql://localhost:3306/test</value>
    </parameter>

  </ResourceParams>
</Context>
```

In general, you should follow the installation instructions that come with your version of Tomcat, as the way you configure datasources in Tomcat changes from time-to-time, and unfortunately if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```
Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null
```

26.3.4.3. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the .jar file that comes with Connector/J to the `lib` directory for your server configuration (which is usually called "`default`"). Then, in the same configuration directory, in the subdirectory named “deploy”, create a datasource configuration file that ends with "-ds.xml", which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```
<datasources>
    <local-tx-datasource>
        <!-- This connection pool will be bound into JNDI with the name
             "java:/MySQLDB" -->

        <jndi-name>MySQLDB</jndi-name>
        <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
        <driver-class>com.mysql.jdbc.Driver</driver-class>
        <user-name>user</user-name>
        <password>pass</password>

        <min-pool-size>5</min-pool-size>

        <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->

        <max-pool-size>20</max-pool-size>

        <!-- Don't allow connections to hang out idle too long,
         never longer than what wait_timeout is set to on the
         server...A few minutes is usually okay here,
         it depends on your application
         and how much spikey load it will see -->

        <idle-timeout-minutes>5</idle-timeout-minutes>

        <!-- If you're using Connector/J 3.1.8 or newer, you can use
             our implementation of these to increase the robustness
             of the connection pool. -->

        <exception-sorter-class-name>com.mysql.jdbc.integration.jboss.ExtendedM
        <valid-connection-checker-class-name>com.mysql.jdbc.integration.jboss.M
```

```
    </local-tx-datasource>
</datasources>
```

26.3.5. Diagnosing Connector/J Problems

This section describes how to solve problems that you may encounter when using Connector/J.

26.3.5.1. Common Problems and Solutions

There are a few issues that seem to be commonly encountered often by users of MySQL Connector/J. This section deals with their symptoms, and their resolutions. If you have further issues, see the "SUPPORT" section.

27.3.5.1.1:

Question:

When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What's going on? I can connect just fine with the MySQL command-line client.

Answer:

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether or not the connection should be allowed.

You must add grants to allow this to happen. The following is an example of how to do this (but not the most secure).

From the mysql command-line client, logged in as a user that can grant privileges, issue the following command:

```
GRANT ALL PRIVILEGES ON [dbname].* to
                '[user]'@'[hostname]' identified by
                '[password]'
```

replacing [dbname] with the name of your database, [user] with the user name, [hostname] with the host that MySQL Connector/J will be connecting from, and [password] with the password you want to use. Be aware that RedHat Linux is broken with respect to the hostname portion for the case when you are connecting from localhost. You need to use "localhost.localdomain" for the [hostname] value in this case. Follow this by issuing the "FLUSH PRIVILEGES" command.

Note

Testing your connectivity with the `mysql` command-line client will not work unless you add the `--host` flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special hostname `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the hostname instead.

Warning

If you don't understand what the 'GRANT' command does, or how it works, you should read and understand the 'General Security Issues and the MySQL Access Privilege System'

[http://www.mysql.com/doc/en/Privilege_system.html] section of the MySQL manual before attempting to change privileges.

Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

27.3.5.1.2:

Question:

My application throws an SQLException 'No Suitable Driver'. Why is this happening?

Answer:

One of two things are happening. Either the driver is not in your CLASSPATH (see the "INSTALLATION" section above), or your URL format is incorrect (see "Developing Applications with MySQL Connector/J").

27.3.5.1.3:

Question:

I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

Answer:

Either you're running an Applet, your MySQL server has been installed with the "--skip-networking" option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the .class files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the "--skip-networking" flag, or if it is firewalled.

If MySQL has been started with the "--skip-networking" option set (the Debian Linux package of MySQL server does this for example), you need to comment it out in the file /etc/mysql/my.cnf or /etc/my.cnf. Of course your my.cnf file might also exist in the `data` directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by MySQL AB always look in /etc/my.cnf and [datadir]/my.cnf. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

27.3.5.1.4:

Question:

I have a servlet/application that works fine for a day, and then stops working overnight

Answer:

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that

handles stale connections or use the "autoReconnect" parameter (see "Developing Applications with MySQL Connector/J").

Also, you should be catching SQLExceptions in your application and dealing with them, rather than propagating them all the way until your application exits, this is just good programming practice. MySQL Connector/J will set the SQLState (see java.sql.SQLException.getSQLState() in your APIDOCS) to "08S01" when it encounters network-connectivity issues during the processing of a query. Your application code should then attempt to re-connect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

Example 26.13. Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
        Connection conn = null;
        Statement stmt = null;
        ResultSet rs = null;

        //
        // How many times do you want to retry the transaction
        // (or at least _getting_ a connection)?
        //
        int retryCount = 5;

        boolean transactionCompleted = false;

        do {
            try {
                conn = getConnection(); // assume getting this from a
                                        // javax.sql.DataSource, or the
                                        // java.sql.DriverManager

                conn.setAutoCommit(false);

                //
                // Okay, at this point, the 'retry-ability' of the
                // transaction really depends on your application logic,
                // whether or not you're using autocommit (in this case
                // not), and whether you're using transacational storage
                // engines
                //
                // For this example, we'll assume that it's _not_ safe
                // to retry the entire transaction, so we set retry count
                // to 0 at this point
                //
                // If you were using exclusively transaction-safe tables,
                // or your application could recover from a connection going
                // bad in the middle of an operation, then you would not
                // touch 'retryCount' here, and just let the loop repeat
                // until retryCount == 0.
                //
                retryCount = 0;

                stmt = conn.createStatement();

                String query = "SELECT foo FROM bar ORDER BY baz";

                rs = stmt.executeQuery(query);

                while (rs.next()) {
                }

                rs.close();
                rs = null;
```

```
                stmt.close();
                stmt = null;

                conn.commit();
                conn.close();
                conn = null;

                transactionCompleted = true;
            } catch (SQLException sqlEx) {

                //
                // The two SQL states that are 'retry-able' are 08S01
                // for a communications error, and 40001 for deadlock.
                //
                // Only retry if the error was due to a stale connection,
                // communications problem or deadlock
                //

                String sqlState = sqlEx.getSQLState();

                if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
                    retryCount--;
                } else {
                    retryCount = 0;
                }
            } finally {
                if (rs != null) {
                    try {
                        rs.close();
                    } catch (SQLException sqlEx) {
                        // You'd probably want to log this . . .
                    }
                }

                if (stmt != null) {
                    try {
                        stmt.close();
                    } catch (SQLException sqlEx) {
                        // You'd probably want to log this as well . . .
                    }
                }

                if (conn != null) {
                    try {
                        //
                        // If we got here, and conn is not null, the
                        // transaction should be rolled back, as not
                        // all work has been done

                        try {
                            conn.rollback();
                        } finally {
                            conn.close();
                        }
                    } catch (SQLException sqlEx) {
                        //
                        // If we got an exception here, something
                        // pretty serious is going on, so we better
                        // pass it up the stack, rather than just
                        // logging it. . .

                        throw sqlEx;
                    }
                }
            }
        } while (!transactionCompleted && (retryCount > 0));
    }
```

27.3.5.1.5:

Question:

I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.

Answer:

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one primary key, the query must select every primary key and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

26.3.5.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is http://bugs.mysql.com/, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you have found a sensitive security bug in MySQL, you can send email to security@mysql.com [mailto:security@mysql.com].

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you don't waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at http://bugs.mysql.com/ [???].

Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details don't matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, ``Why doesn't this work for me?'' Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, you should create a repeatable, stanalone testcase that doesn't involve any third-party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named '`com.mysql.jdbc.util.BaseBugReport`'. To create a testcase for Connector/J using this

class, create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest` ().

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest` () method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, you should use one of the variants of the `getConnection` () method to create a JDBC connection to MySQL:

- getConnection() - Provides a connection to the JDBC URL specified in getUrl(). If a connection already exists, that connection is returned, otherwise a new connection is created.
- getNewConnection() - Use this if you need to get a new connection for your bug report (i.e. there's more than one connection involved).
- getConnection(String url) - Returns a connection using the given URL.
- getConnection(String url, Properties props) - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different than 'jdbc:mysql:///test', then override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main` () method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
      new MyBugReport().run();
 }
```

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to http://bugs.mysql.com/.

26.3.6. MySQL Connector/J Change History

```
12-22-05 - Version 5.0.0-beta

    - XADataSource implemented (ported from 3.2 branch which won't be
      released as a product). Use
      "com.mysql.jdbc.jdbc2.optional.MysqlXADataSource" as your datasource
      class name in your application server to utilize XA transactions
      in MySQL-5.0.10 and newer.

    - PreparedStatement.setString() didn't work correctly when
      sql_mode on server contained NO_BACKSLASH_ESCAPES, and no characters
      that needed escaping were present in the string.

    - Attempt detection of the MySQL type "BINARY" (it's an alias, so this isn'
      always reliable), and use the java.sql.Types.BINARY type mapping for it.

    - Moved -bin-g.jar file into separate "debug" subdirectory to avoid confusi

    - Don't allow .setAutoCommit(true), or .commit() or .rollback() on an XA-ma
```

```
      connection as-per the JDBC specification.

    - If the connection "useTimezone" is set to "true", then also respect timez
      conversions in escape-processed string literals (e.g. "{ts ...}" and
      "{t ...}").

    - Return original column name for RSMD.getColumnName() if the column was al
      alias name for .getColumnLabel() (if aliased), and original table name
      for .getTableName(). Note this only works for MySQL-4.1 and newer, as
      older servers don't make this information available to clients.

    - Setting "useJDBCCompliantTimezoneShift=true" (it's not the default)
      causes the driver to use GMT for _all_ TIMESTAMP/DATETIME timezones,
      and the current VM timezone for any other type that refers to timezones.
      This feature can not be used when "useTimezone=true" to convert between
      server and client timezones.

    - Add one level of indirection of internal representation of CallableStatem
      parameter metadata to avoid class not found issues on JDK-1.3 for
      ParameterMetadata interface (which doesn't exist prior to JDBC-3.0).

    - Added unit tests for XADatasource, as well as friendlier exceptions
      for XA failures compared to the "stock" XAException (which has no
      messages).

    - Fixed BUG#14279 [http://bugs.mysql.com/14279] - Idle timeouts cause XACon
      themselves back

    - Added support for Connector/MXJ integration via url subprotocol
      "jdbc:mysql:mxj://....".

    - Moved all SQLException constructor usage to a factory in SQLError
      (ground-work for JDBC-4.0 SQLState-based exception classes).

    - Removed Java5-specific calls to BigDecimal constructor (when
      result set value is '', (int)0 was being used as an argument
      in-directly via method return value. This signature doesn't exist
      prior to Java5.)

    - Moved all SQLException creation to a factory method in SQLError,
      groundwork for JDBC-4.0 SQLState class-based exceptions.

    - Added service-provider entry to META-INF/services/java.sql.Driver
      for JDBC-4.0 support.

    - Return "[VAR]BINARY" for RSMD.getColumnTypeName() when that is actually
      the type, and it can be distinguished (MySQL-4.1 and newer).

    - When fix for BUG#14562 [http://bugs.mysql.com/14562] was merged from 3.1.
      for CallableStatement's parameter metadata to return correct
      information for .getParameterClassName().

    - Fuller synchronization of Connection to avoid deadlocks when
      using multithreaded frameworks that multithread a single connection
      (usually not recommended, but the JDBC spec allows it anyways),
      part of fix to BUG#14972 [http://bugs.mysql.com/14972]).

    - Implementation of Statement.cancel() and Statement.setQueryTimeout().
      Both require MySQL-5.0.0 or newer server, require a separate connection
      to issue the "KILL QUERY" command, and in the case of setQueryTimeout()
      creates an additional thread to handle the timeout functionality.

      Note: Failures to cancel the statement for setQueryTimeout() may manifest
      themselves as RuntimeExceptions rather than failing silently, as there
      is currently no way to unblock the thread that is executing the query bei
      cancelled due to timeout expiration and have it throw the exception
      instead.

xx-xx-05 - Version 3.1.13
```

```
    - Fixed BUG#15464 [http://bugs.mysql.com/15464] - INOUT parameter does not

    - Fixed BUG#14609 [http://bugs.mysql.com/14609] - Exception thrown for new
      using updatable result sets.

    - Fixed BUG#15544 [http://bugs.mysql.com/15544], no "dos" character set in

    - Fixed BUG#15383 [http://bugs.mysql.com/15383] - PreparedStatement.setObje
      BigInteger as object, rather than sending as numeric value
      (and is thus not complementary to .getObject() on an UNSIGNED
      LONG type).

    - Fixed BUG#11874 [http://bugs.mysql.com/11874] - ResultSet.getShort() for
      returned wrong values.

    - Fixed BUG#15676 [http://bugs.mysql.com/15676] - lib-nodist directory miss
      package breaks out-of-box build

    - Fixed BUG#15854 [http://bugs.mysql.com/15854] - DBMD.getColumns() returns

11-30-05 - Version 3.1.12

    - Fixed client-side prepared statement bug with embedded ? inside
      quoted identifiers (it was recognized as a placeholder, when it
      was not).

    - Don't allow executeBatch() for CallableStatements with registered
      OUT/INOUT parameters (JDBC compliance).

    - Fall back to platform-encoding for URLDecoder.decode() when
      parsing driver URL properties if the platform doesn't have a
      two-argument version of this method.

    - Fixed BUG#14562 [http://bugs.mysql.com/14562] - Java type conversion may
      mediumint.

    - Added configuration property "useGmtMillisForDatetimes" which
      when set to true causes ResultSet.getDate(), .getTimestamp() to
      return correct millis-since GMT when .getTime() is called on
      the return value (currently default is "false" for legacy
      behavior).

    - Fixed DatabaseMetaData.stores*Identifiers():

        * if lower_case_table_names=0 (on server):

            storesLowerCaseIdentifiers() returns false
            storesLowerCaseQuotedIdentifiers() returns false
            storesMixedCaseIdentifiers() returns true
            storesMixedCaseQuotedIdentifiers() returns true
            storesUpperCaseIdentifiers() returns false
            storesUpperCaseQuotedIdentifiers() returns true

        * if lower_case_table_names=1 (on server):

            storesLowerCaseIdentifiers() returns true
            storesLowerCaseQuotedIdentifiers() returns true
            storesMixedCaseIdentifiers() returns false
            storesMixedCaseQuotedIdentifiers() returns false
            storesUpperCaseIdentifiers() returns false
            storesUpperCaseQuotedIdentifiers() returns true

    - Fixed BUG#14815 [http://bugs.mysql.com/14815] - DatabaseMetaData.getColum
      return TABLE_NAME correctly.

    - Fixed BUG#14909 [http://bugs.mysql.com/14909] - escape processor replaces
      in quoted string with string delimiter.

    - Fixed BUG#12975 [http://bugs.mysql.com/12975] - OpenOffice expects
```

```
      DBMD.supportsIntegrityEnhancementFacility() to return "true"
      if foreign keys are supported by the datasource, even though
      this method also covers support for check constraints,
      which MySQL _doesn't_ have. Setting the configuration property
      "overrideSupportsIntegrityEnhancementFacility" to "true" causes
      the driver to return "true" for this method.

    - Added "com.mysql.jdbc.testsuite.url.default" system property to
      set default JDBC url for testsuite (to speed up bug resolution
      when I'm working in Eclipse).

    - Fixed BUG#14938 [http://bugs.mysql.com/14938] - Unable to initialize chara
      tables (due to J2EE classloader differences).

    - Fixed BUG#14972 [http://bugs.mysql.com/14972] - Deadlock while closing se
      statements from multiple threads sharing one connection.

    - Fixed BUG#12230 [http://bugs.mysql.com/12230] - logSlowQueries should give

    - Fixed BUG#13775 [http://bugs.mysql.com/13775] - Extraneous sleep on autoR

    - Fixed BUG#15024 [http://bugs.mysql.com/15024] - Driver incorrectly closes
      arguments to PreparedStatements. Reverts to legacy behavior by
      setting the JDBC configuration property "autoClosePStmtStreams"
      to "true" (also included in the 3-0-Compat configuration "bundle").

    - Fixed BUG#13048 [http://bugs.mysql.com/13048] - maxQuerySizeToLog is not
      bound values for execute() phase of server-side prepared statements
      when profileSQL=true as well.

    - Fixed BUG#15065 [http://bugs.mysql.com/15065] - Usage advisor complains a
      columns, even though they've been referenced.

    - Don't increase timeout for failover/reconnect (BUG#6577 [http://bugs.mysq

    - Process escape tokens in Connection.prepareStatement(...), fix
      for BUG#15141 [http://bugs.mysql.com/15141]. You can disable this behavio
      the JDBC URL configuration property "processEscapeCodesForPrepStmts"
      to "false".

    - Fixed BUG#13255 [http://bugs.mysql.com/13255] - Reconnect during middle o
      should not occur if autoReconnect is enabled.

10-07-05 - Version 3.1.11-stable

    - Fixed BUG#11629 [http://bugs.mysql.com/11629] - Spurious "!" on console w
      encoding is "utf8".

    - Fixed statements generated for testcases missing ";" for
      "plain" statements.

    - Fixed BUG#11663 [http://bugs.mysql.com/11663] - Incorrect generation of t
      for server-side prepared statements.

    - Fixed regression caused by fix for BUG#11552 [http://bugs.mysql.com/11552
      to return incorrect values for unsigned integers when those
      integers where within the range of the positive signed type.

    - Moved source code to svn repo.

    - Fixed BUG#11797 [http://bugs.mysql.com/11797] - Escape tokenizer doesn't
      for escapes.

    - GEOMETRY type not recognized when using server-side prepared statements.

    - Fixed BUG#11879 [http://bugs.mysql.com/11879] -- ReplicationConnection wo
      "Catalog can't be null" exception.

    - Fixed BUG#12218 [http://bugs.mysql.com/12218], properties shared between
      replication connection.
```

- Fixed BUG#10630 [http://bugs.mysql.com/10630], Statement.getWarnings() fa
  has been closed.

- Only get char[] from SQL in PreparedStatement.ParseInfo() when needed.

- Fixed BUG#12104 [http://bugs.mysql.com/12104] - Geometry types not handle
  statements.

- Fixed BUG#11614 [http://bugs.mysql.com/11614] - StringUtils.getBytes() do
  multibyte character encodings and a length in _characters_ is
  specified.

- Fixed BUG#11798 [http://bugs.mysql.com/11798] - Pstmt.setObject(...., Typ

- Fixed BUG#11976 [http://bugs.mysql.com/11976] - maxPerformance.properties
  "elideSetAutoCommits".

- Fixed BUG#11575 [http://bugs.mysql.com/11575] -- DBMD.storesLower/Mixed/U
  reports incorrect values for servers deployed on Windows.

- Fixed BUG#11190 [http://bugs.mysql.com/11190] - ResultSet.moveToCurrentRo
  preceded by a call to ResultSet.moveToInsertRow().

- Fixed BUG#11115 [http://bugs.mysql.com/11115], VARBINARY data corrupted w
  prepared statements and .setBytes().

- Fixed BUG#12229 [http://bugs.mysql.com/12229] - explainSlowQueries hangs
  prepared statements.

- Fixed BUG#11498 [http://bugs.mysql.com/11498] - Escape processor didn't h
  with double quotes.

- Lifted restriction of changing streaming parameters with server-side
  prepared statements. As long as _all_ streaming parameters were set
  before execution, .clearParameters() does not have to be called.
  (due to limitation of client/server protocol, prepared statements
   can not reset _individual_ stream data on the server side).

- Reworked Field class, *Buffer, and MysqlIO to be aware of field
  lengths > Integer.MAX_VALUE.

- Updated DBMD.supportsCorrelatedQueries() to return true for versions >
  4.1, supportsGroupByUnrelated() to return true and
  getResultSetHoldability() to return HOLD_CURSORS_OVER_COMMIT.

- Fixed BUG#12541 [http://bugs.mysql.com/12541] - Handling of catalog argum
  DatabaseMetaData.getIndexInfo(), which also means changes to the followin
  methods in DatabaseMetaData:

- getBestRowIdentifier()
- getColumns()
- getCrossReference()
- getExportedKeys()
- getImportedKeys()
- getIndexInfo()
- getPrimaryKeys()
- getProcedures() (and thus indirectly getProcedureColumns())
- getTables()

  The "catalog" argument in all of these methods now behaves in the followi
  way:

    - Specifying NULL means that catalog will not be used to filter the
      results (thus all databases will be searched), unless you've
      set "nullCatalogMeansCurrent=true" in your JDBC URL properties.

    - Specifying "" means "current" catalog, even though this isn't quite
      JDBC spec compliant, it's there for legacy users.

    - Specifying a catalog works as stated in the API docs.

    - Made Connection.clientPrepare() available from "wrapped" connections in the jdbc2.optional package (connections built by ConnectionPoolDataSource instances).

- Added Connection.isMasterConnection() for clients to be able to determine if a multi-host master/slave connection is connected to the first host in the list.

- Fixed BUG#12753 [http://bugs.mysql.com/12753] - Tokenizer for "=" in URL sessionVariables=.... to be parameterized incorrectly.

- Fixed BUG#11781 [http://bugs.mysql.com/11781], foreign key information tha parsed incorrectly when DatabaseMetaData methods use that information.

- The "sendBlobChunkSize" property is now clamped to "max_allowed_packet" with consideration of stream buffer size and packet headers to avoid PacketTooBigExceptions when "max_allowed_packet" is similar in size to the default "sendBlobChunkSize" which is 1M.

- CallableStatement.clearParameters() now clears resources associated with INOUT/OUTPUT parameters as well as INPUT parameters.

- Fixed BUG#12417 [http://bugs.mysql.com/12417] - Connection.prepareCall() case-sensitive (on Windows systems).

- Fixed BUG#12752 [http://bugs.mysql.com/12752] - Cp1251 incorrectly mapped servers newer than 4.0.x.

- Fixed BUG#12970 [http://bugs.mysql.com/12970] - java.sql.Types.OTHER retu BINARY and VARBINARY columns when using DatabaseMetaData.getColumns().

- ServerPreparedStatement.getBinding() now checks if the statement is closed before attempting to reference the list of parameter bindings, to avoid throwing a NullPointerException.

- Fixed BUG#13277 [http://bugs.mysql.com/13277] - ResultSetMetaData from Statement.getGeneratedKeys() caused NullPointerExceptions to be thrown whenever a method that required a connection reference was called.

- Backport of Field class, ResultSetMetaData.getColumnClassName(), and ResultSet.getObject(int) changes from 5.0 branch to fix behavior surrounding VARCHAR BINARY/VARBINARY and related types.

- Fixed NullPointerException when converting "catalog" parameter in many DatabaseMetaDataMethods to byte[]s (for the result set) when the parameter is null. ("null" isn't technically allowed by the JDBC specification, but we've historically allowed it).

- Backport of VAR[BINARY|CHAR] [BINARY] types detection from 5.0 branch.

- Read response in MysqlIO.sendFileToServer(), even if the local file can't be opened, otherwise next query issued will fail, because it's reading the response to the empty LOAD DATA INFILE packet sent to the server.

- Workaround for BUG#13374 [http://bugs.mysql.com/13374] - ResultSet.getSta on closed result set returns NULL (as per JDBC 4.0 spec, but not backward-compatible). Set the connection property "retainStatementAfterResultSetClose" to "true" to be able to retrieve a ResultSet's statement after the ResultSet has been closed via .getStatement() (the default is "false", to be JDBC-compliant and to reduce the chance that code using JDBC leaks Statement instances).

```
    - Fixed BUG#13453 [http://bugs.mysql.com/13453] - URL configuration paramet
      '&' or '=' in their values. The JDBC driver now parses
      configuration parameters as if they are encoded using the
      application/x-www-form-urlencoded format as specified
      by java.net.URLDecoder -
      http://java.sun.com/j2se/1.5.0/docs/api/java/net/URLDecoder.html

      If the '%' character is present in a configuration property,
      it must now be represented as %25, which is the encoded form
      of '%' when using application/x-www-form-urlencoded encoding.

    - The configuration property "sessionVariables" now allows you to
      specify variables that start with the "@" sign.

    - Fixed BUG#13043 [http://bugs.mysql.com/13043] - when 'gatherPerfMetrics' i
      servers older than 4.1.0, a NullPointerException is thrown from
      the constructor of ResultSet if the query doesn't use any tables.

06-23-05 - Version 3.1.10-stable

    - Fixed connecting without a database specified raised an exception
      in MysqlIO.changeDatabaseTo().

    - Initial implemention of ParameterMetadata for
      PreparedStatement.getParameterMetadata(). Only works fully
      for CallableStatements, as current server-side prepared statements
      return every parameter as a VARCHAR type.

06-22-05 - Version 3.1.9-stable

    - Overhaul of character set configuration, everything now
      lives in a properties file.

    - Driver now correctly uses CP932 if available on the server
      for Windows-31J, CP932 and MS932 java encoding names,
      otherwise it resorts to SJIS, which is only a close
      approximation. Currently only MySQL-5.0.3 and newer (and
      MySQL-4.1.12 or .13, depending on when the character set
      gets backported) can reliably support any variant of CP932.

    - Fixed BUG#9064 [http://bugs.mysql.com/9064] - com.mysql.jdbc.PreparedStat
      does unnecessary call to toCharArray().

    - Fixed Bug#10144 [http://bugs.mysql.com/10144] - Memory leak in ServerPrepa
      serverPrepare() fails.

    - Actually write manifest file to correct place so it ends up
      in the binary jar file.

    - Added "createDatabaseIfNotExist" property (default is "false"),
      which will cause the driver to ask the server to create the
      database specified in the URL if it doesn't exist. You must have
      the appropriate privileges for database creation for this to
      work.

    - Fixed BUG#10156 [http://bugs.mysql.com/10156] - Unsigned SMALLINT treated
      fixed all cases for UNSIGNED integer values and server-side prepared stat
      as well as ResultSet.getObject() for UNSIGNED TINYINT.

    - Fixed BUG#10155 [http://bugs.mysql.com/10155], double quotes not recogniz
      client-side prepared statements.

    - Made enableStreamingResults() visible on
      com.mysql.jdbc.jdbc2.optional.StatementWrapper.

    - Made ServerPreparedStatement.asSql() work correctly so auto-explain
      functionality would work with server-side prepared statements.

    - Made JDBC2-compliant wrappers public in order to allow access to
```

vendor extensions.

- Cleaned up logging of profiler events, moved code to dump a profiler event as a string to com.mysql.jdbc.log.LogUtils so that third parties can use it.

- DatabaseMetaData.supportsMultipleOpenResults() now returns true. The driver has supported this for some time, DBMD just missed that fact.

- Fixed BUG#10310 [http://bugs.mysql.com/10310] - Driver doesn't support {?= stored functions. This involved adding support for function retrieval to DatabaseMetaData.getProcedures() and getProcedureColumns() as well.

- Fixed BUG#10485 [http://bugs.mysql.com/10485], SQLException thrown when r with ResultSet.getString(). The driver will now always treat YEAR types as java.sql.Dates and return the correct values for getString(). Alternatively, the "yearIsDateType" connection property can be set to "false" and the values will be treated as SHORTs.

- The datatype returned for TINYINT(1) columns when "tinyInt1isBit=true" (the default) can be switched between Types.BOOLEAN and Types.BIT using the new configuration property "transformedBitIsBoolean", which defaults to "false". If set to "false" (the default), DatabaseMetaData.getColumns() and ResultSetMetaData.getColumnType() will return Types.BOOLEAN for TINYINT(1) columns. If "true", Types.BOOLEAN will be returned instead. Irregardless of this configuratio property, if "tinyInt1isBit" is enabled, columns with the type TINYINT(1) will be returned as java.lang.Boolean instances from ResultSet.getObject(..), and ResultSetMetaData.getColumnClassName() will return "java.lang.Boolean".

- Fixed BUG#10496 [http://bugs.mysql.com/10496] - SQLException is thrown wh "characterSetResults" with cp932 or eucjpms.

- Reorganized directory layout, sources now in "src" folder, don't pollute parent directory when building, now output goes to "./build", distribution goes to "./dist".

- Added support/bug hunting feature that generates .sql test scripts to STDERR when "autoGenerateTestcaseScript" is set to "true".

- Fixed BUG#10850 [http://bugs.mysql.com/10850] - 0-length streams not sent using server-side prepared statements.

- Setting "cachePrepStmts=true" now causes the Connection to also cache the check the driver performs to determine if a prepared statement can be server-side or not, as well as caches server-side prepared statements for the lifetime of a connection. As before, the "prepStmtCacheSize" parameter controls the size of these caches.

- Try to handle OutOfMemoryErrors more gracefully. Although not much can be done, they will in most cases close the connection they happened on so that further operations don't run into a connection in some unknown state. When an OOM has happened, any further operations on the connection will fail with a "Connection closed" exception that will also list the OOM exception as the reason for the implicit connection close event.

- Don't send COM_RESET_STMT for each execution of a server-side prepared statement if it isn't required.

- Driver detects if you're running MySQL-5.0.7 or later, and does not scan for "LIMIT ?[,?]" in statements being prepared, as the server supports those types of queries now.

- Fixed BUG#11115 [http://bugs.mysql.com/11115], Varbinary data corrupted w prepared statements and ResultSet.getBytes().

- Connection.setCatalog() is now aware of the "useLocalSessionState" configuration property, which when set to true will prevent the driver from sending "USE ..." to the server if the requested catalog is the same as the current catalog.

- Added the following configuration bundles, use one or many via the "useConfigs" configuration property:

  * maxPerformance -- maximum performance without being reckless
  * solarisMaxPerformance -- maximum performance for Solaris, avoids syscalls where it can
  * 3-0-Compat -- Compatibility with Connector/J 3.0.x functionality

- Added "maintainTimeStats" configuration property (defaults to "true"), which tells the driver whether or not to keep track of the last query time and the last successful packet sent to the server's time. If set to false, removes two syscalls per query.

- Fixed BUG#11259 [http://bugs.mysql.com/11259], autoReconnect ping causes startup.

- Fixed BUG#11360 [http://bugs.mysql.com/11360] Connector/J dumping query i

- Fixed PreparedStatement.setClob() not accepting null as a parameter.

- Fixed BUG#11411 [http://bugs.mysql.com/11411] - Production package doesn' classes.

- Removed nonsensical "costly type conversion" warnings when using usage advisor.

04-14-05 - Version 3.1.8-stable

- Fixed DatabaseMetaData.getTables() returning views when they were not asked for as one of the requested table types.

- Added support for new precision-math DECIMAL type in MySQL >= 5.0.3.

- Fixed ResultSet.getTime() on a NULL value for server-side prepared statements throws NPE.

- Made Connection.ping() a public method.

- Fixed Bug#8868 [http://bugs.mysql.com/8868], DATE_FORMAT() queries return

- ServerPreparedStatements now correctly 'stream' BLOB/CLOB data to the server. You can configure the threshold chunk size using the JDBC URL property 'blobSendChunkSize' (the default is one megabyte).

- BlobFromLocator now uses correct identifier quoting when generating prepared statements.

- Server-side session variables can be preset at connection time by passing them as a comma-delimited list for the connection property 'sessionVariables'.

- Fixed regression in ping() for users using autoReconnect=true.

- Fixed BUG#9040 [http://bugs.mysql.com/9040] - PreparedStatement.addBatch(prepared statements and streaming BINARY data.

- Fixed BUG#8800 [http://bugs.mysql.com/8800] - DBMD.supportsMixedCase*Iden value on servers running on case-sensitive filesystems.

- Fixed BUG#9206 [http://bugs.mysql.com/9206], can not use 'UTF-8' for chara configuration property.

- Fixed BUG#9236 [http://bugs.mysql.com/9236], a continuation of BUG#8868 [that should return non-string types when resolved by temporary tables sud

become opaque binary strings (work-around for server limitation). Also fi
fields with type of CHAR(n) CHARACTER SET BINARY to return correct/matchi
classes for RSMD.getColumnClassName() and ResultSet.getObject().

- Fixed BUG#8792 [http://bugs.mysql.com/8792] - DBMD.supportsResultSetConcu
true for forward-only/read-only result sets (we obviously support this).

- Fixed BUG#8803 [http://bugs.mysql.com/8803], 'DATA_TYPE' column from DBMD
causes ArrayIndexOutOfBoundsException when accessed (and in fact, didn't
return any value).

- Check for empty strings ('') when converting char/varchar column data to
throw exception if 'emptyStringsConvertToZero' configuration property is
to 'false' (for backward-compatibility with 3.0, it is now set to 'true'
by default, but will most likely default to 'false' in 3.2).

- Fixed BUG#9320 [http://bugs.mysql.com/9320] - PreparedStatement.getMetaDa
under certain conditions when not using server-side prepared statements.

- Connection.canHandleAsPreparedStatement() now makes 'best effort' to dist
LIMIT clauses with placeholders in them from ones without in order to hav
false positives when generating work-arounds for statements the server ca
currently handle as server-side prepared statements.

- Fixed build.xml to not compile log4j logging if log4j not available.

- Added support for the c3p0 connection pool's (http://c3p0.sf.net/)
validation/connection checker interface which uses the lightweight
'COM_PING' call to the server if available. To use it, configure your
c3p0 connection pool's 'connectionTesterClassName' property to use
'com.mysql.jdbc.integration.c3p0.MysqlConnectionTester'.

- Better detection of LIMIT inside/outside of quoted strings so that
the driver can more correctly determine whether a prepared statement
can be prepared on the server or not.

- Fixed BUG#9319 [http://bugs.mysql.com/9319] - Stored procedures with same
different databases confuse the driver when it tries to determine
parameter counts/types.

- Added finalizers to ResultSet and Statement implementations to be JDBC
spec-compliant, which requires that if not explicitly closed, these
resources should be closed upon garbage collection.

- Fixed BUG#9682 [http://bugs.mysql.com/9682] - Stored procedures with DECI
storage specifications that contained "," in them would fail.

- PreparedStatement.setObject(int, Object, int type, int scale) now
uses scale value for BigDecimal instances.

- Fixed BUG#9704 [http://bugs.mysql.com/9704] - Statement.getMoreResults()
existing result set was .close()d.

- The performance metrics feature now gathers information about
number of tables referenced in a SELECT.

- The logging system is now automatically configured. If the value has
been set by the user, via the URL property "logger" or the system
property "com.mysql.jdbc.logger", then use that, otherwise, autodetect
it using the following steps:

    Log4j, if it's available,
    Then JDK1.4 logging,
    Then fallback to our STDERR logging.

- Fixed BUG#9778 [http://bugs.mysql.com/9778], DBMD.getTables() shouldn't r
are asked for, even if the database version doesn't support views.

- Fixed driver not returning 'true' for '-1' when ResultSet.getBoolean()
was called on result sets returned from server-side prepared statements.

```
    - Added a Manifest.MF file with implementation information to the .jar
      file.

    - More tests in Field.isOpaqueBinary() to distinguish opaque binary (i.e.
      fields with type CHAR(n) and CHARACTER SET BINARY) from output of
      various scalar and aggregate functions that return strings.

    - Fixed BUG#9917 [http://bugs.mysql.com/9917] - Should accept null for cata
      in DBMD methods, even though it's not JDBC-compliant for legacy's sake.
      Disable by setting connection property "nullCatalogMeansCurrent" to "fals
      (which will be the default value in C/J 3.2.x).

    - Fixed BUG#9769 [http://bugs.mysql.com/9769] - Should accept null for name
      even though it isn't JDBC compliant, for legacy's sake. Disable by settin
      connection property "nullNamePatternMatchesAll" to "false" (which will be
      the default value in C/J 3.2.x).

02-18-05 - Version 3.1.7-stable

    - Fixed BUG#7686 [http://bugs.mysql.com/7686], Timestamp key column data ne
      stripped for UpdatableResultSet.refreshRow().

    - Fixed BUG#7715 [http://bugs.mysql.com/7715] - Timestamps converted incorr
      with Server-side prepared statements and updatable result sets.

    - Detect new sql_mode variable in string form (it used to be
      integer) and adjust quoting method for strings appropriately.

    - Added 'holdResultsOpenOverStatementClose' property (default is
      false), that keeps result sets open over statement.close() or new
      execution on same statement (suggested by Kevin Burton).

    - Fixed BUG#7952 [http://bugs.mysql.com/7952] -- Infinite recursion when 'f
      in failover configuration.

    - Disable multi-statements (if enabled) for MySQL-4.1 versions prior
      to version 4.1.10 if the query cache is enabled, as the server
      returns wrong results in this configuration.

    - Fixed duplicated code in configureClientCharset() that prevented
      useOldUTF8Behavior=true from working properly.

    - Removed 'dontUnpackBinaryResults' functionality, the driver now
      always stores results from server-side prepared statements as-is
      from the server and unpacks them on demand.

    - Fixed BUG#8096 [http://bugs.mysql.com/8096] where emulated locators corru
      when using server-side prepared statements.

    - Fixed synchronization issue with
      ServerPreparedStatement.serverPrepare() that could cause
      deadlocks/crashes if connection was shared between threads.

    - By default, the driver now scans SQL you are preparing via all
      variants of Connection.prepareStatement() to determine if it is a
      supported type of statement to prepare on the server side, and if
      it is not supported by the server, it instead prepares it as a
      client-side emulated prepared statement (BUG#4718 [http://bugs.mysql.com/4
      disable this by passing 'emulateUnsupportedPstmts=false' in your
      JDBC URL.

    - Remove _binary introducer from parameters used as in/out
      parameters in CallableStatement.

    - Always return byte[]s for output parameters registered as *BINARY.

    - Send correct value for 'boolean' "true" to server for
      PreparedStatement.setObject(n, "true", Types.BIT).
```

- Fixed bug with Connection not caching statements from prepareStatement() when the statement wasn't a server-side prepared statement.

- Choose correct 'direction' to apply time adjustments when both client and server are in GMT timezone when using ResultSet.get(..., cal) and PreparedStatement.set(...., cal).

- Added 'dontTrackOpenResources' option (default is false, to be JDBC compliant), which helps with memory use for non-well-behaved apps (i.e applications which don't close Statements when they should).

- Fixed BUG#8428 [http://bugs.mysql.com/8428] - ResultSet.getString() doesn stored on server, bug fix only enabled when 'noDatetimeStringSync' property is set to 'true' (the default is 'false').

- Fixed NPE in ResultSet.realClose() when using usage advisor and result set was already closed.

- Fixed BUG#8487 [http://bugs.mysql.com/8487] - PreparedStatements not crea sets.

- Don't pass NULL to String.valueOf() in ResultSet.getNativeConvertToString(), as it stringifies it (i.e. returns "null"), which is not correct for the method in question.

- Fixed BUG#8484 [http://bugs.mysql.com/8484] - ResultSet.getBigDecimal() t when rounding would need to occur to set scale. The driver now chooses a rounding mode of 'half up' if non-rounding BigDecimal.setScale() fails.

- Added 'useLocalSessionState' configuration property, when set to 'true' the JDBC driver trusts that the application is well-behaved and only sets autocommit and transaction isolation levels using the methods provided on java.sql.Connection, and therefore can manipulate these values in many cases without incurring round-trips to the database server.

- Added enableStreamingResults() to Statement for connection pool implementations that check Statement.setFetchSize() for specification-compliant values. Call Statement.setFetchSize(>=0) to disable the streaming results for that statement.

- Added support for BIT type in MySQL-5.0.3. The driver will treat BIT(1-8) as the JDBC standard BIT type (which maps to java.lang.Boolean), as the server does not currently send enough information to determine the size of a bitfield when < 9 bits are declared. BIT(>9) will be treated as VARBINARY, and will return byte[] when getObject() is called.

12-23-04 - Version 3.1.6-stable

- Fixed hang on SocketInputStream.read() with Statement.setMaxRows() and multiple result sets when driver has to truncate result set directly, rather than tacking a 'LIMIT n' on the end of it.

- Fixed BUG#7026 [http://bugs.mysql.com/7026] - DBMD.getProcedures() doesn'

12-02-04 - Version 3.1.5-gamma

- Fix comparisons made between string constants and dynamic strings that are either toUpperCase()d or toLowerCase()d to use Locale.ENGLISH, as some locales 'override' case rules for English. Also use StringUtils.indexOfIgnoreCase() instead of .toUpperCase().indexOf(), avoids creating a very short-lived transient String instance.

- Fixed BUG#5235 [http://bugs.mysql.com/5235] - Server-side prepared statem 'zeroDateTimeBehavior' property, and would cause class-cast exceptions when using ResultSet.getObject(), as the all-zero string

was always returned.

- Fixed batched updates with server prepared statements weren't looking if the types had changed for a given batched set of parameters compared to the previous set, causing the server to return the error 'Wrong arguments to mysql_stmt_execute()'.

- Handle case when string representation of timestamp contains trailing '.' with no numbers following it.

- Fixed BUG#5706 [http://bugs.mysql.com/5706] - Inefficient detection of pr in ResultSet.getNativeString().

- Don't throw exceptions for Connection.releaseSavepoint().

- Use a per-session Calendar instance by default when decoding dates from ServerPreparedStatements (set to old, less performant behavior by setting property 'dynamicCalendars=true').

- Added experimental configuration property 'dontUnpackBinaryResults', which delays unpacking binary result set values until they're asked for, and only creates object instances for non-numerical values (it is set to 'false' by default). For some usecase/jvm combinations, this is friendlier on the garbage collector.

- Fixed BUG#5729 [http://bugs.mysql.com/5729] - UNSIGNED BIGINT unpacked in server-side prepared statement result sets.

- Fixed BUG#6225 [http://bugs.mysql.com/6225] - ServerSidePreparedStatement objects un-necessarily.

- Removed un-wanted new Throwable() in ResultSet constructor due to bad merge (caused a new object instance that was never used for every result set created) - Found while profiling for BUG#6359 [http://bugs.mysql.com/

- Fixed too-early creation of StringBuffer in EscapeProcessor.escapeSQL(), also return String when escaping not needed (to avoid unnecssary object allocations). Found while profiling for BUG#6359 [http://bugs.mysql.com/6

- Use null-safe-equals for key comparisons in updatable result sets.

- Fixed BUG#6537 [http://bugs.mysql.com/6537], SUM() on Decimal with server scale if zero-padding is needed (this ends up being due to conversion to by server, which when converted to a string to parse into BigDecimal, los 'padding' zeros).

- Use DatabaseMetaData.getIdentifierQuoteString() when building DBMD queries.

- Use 1MB packet for sending file for LOAD DATA LOCAL INFILE if that is < 'max_allowed_packet' on server.

- Fixed BUG#6399 [http://bugs.mysql.com/6399], ResultSetMetaData.getColumnD values for multi-byte charsets.

- Make auto-deserialization of java.lang.Objects stored in BLOBs configurable via 'autoDeserialize' property (defaults to 'false').

- Re-work Field.isOpaqueBinary() to detect 'CHAR(n) CHARACTER SET BINARY' to support fixed-length binary fields for ResultSet.getObject().

- Use our own implementation of buffered input streams to get around blocking behavior of java.io.BufferedInputStream. Disable this with 'useReadAheadInput=false'.

- Fixed BUG#6348 [http://bugs.mysql.com/6348], failing to connect to the se addresses for the given host name is IPV6 (which the server does not yet bind on). The driver now loops through _all_ IP addresses for a given host, and stops on the first one that accepts() a socket.connect().

09-04-04 - Version 3.1.4-beta

- Fixed BUG#4510 [http://bugs.mysql.com/4510] - connector/j 3.1.3 beta does
  correctly (caused by changes to support unsigned reads in
  Buffer.readInt() -> Buffer.readShort()).

- Added support in DatabaseMetaData.getTables() and getTableTypes()
  for VIEWs which are now available in MySQL server version 5.0.x.

- Fixed BUG#4642 [http://bugs.mysql.com/4642] -- ServerPreparedStatement.ex
  threw ArrayIndexOutOfBoundsException when unpacking field metadata.

- Optimized integer number parsing, enable 'old' slower integer parsing
  using JDK classes via 'useFastIntParsing=false' property.

- Added 'useOnlyServerErrorMessages' property, which causes message text
  in exceptions generated by the server to only contain the text sent by
  the server (as opposed to the SQLState's 'standard' description, followed
  by the server's error message). This property is set to 'true' by default

- Fixed BUG#4689 [http://bugs.mysql.com/4689] - ResultSet.wasNull() does no
  previous null was returned.

- Track packet sequence numbers if enablePacketDebug=true, and throw an
  exception if packets received out-of-order.

- Fixed BUG#4482 [http://bugs.mysql.com/4482], ResultSet.getObject() return
  when using prepared statements.

- Calling MysqlPooledConnection.close() twice (even though an application
  error), caused NPE. Fixed.

- Fixed BUG#5012 [http://bugs.mysql.com/5012] -- ServerPreparedStatements d
  DECIMAL type don't work.

- Fixed BUG#5032 [http://bugs.mysql.com/5032] -- ResultSet.getObject() does
  type Boolean for pseudo-bit types from prepared statements on 4.1.x
  (shortcut for avoiding extra type conversion when using binary-encoded
  result sets obscurred test in getObject() for 'pseudo' bit type)

- You can now use URLs in 'LOAD DATA LOCAL INFILE' statements, and the
  driver will use Java's built-in handlers for retreiving the data and
  sending it to the server. This feature is not enabled by default,
  you must set the 'allowUrlInLocalInfile' connection property to 'true'.

- The driver is more strict about truncation of numerics on
  ResultSet.get*(), and will throw an SQLException when truncation is
  detected. You can disable this by setting 'jdbcCompliantTruncation' to
  false (it is enabled by default, as this functionality is required
  for JDBC compliance).

- Added three ways to deal with all-zero datetimes when reading them from
  a ResultSet, 'exception' (the default), which throws an SQLException
  with an SQLState of 'S1009', 'convertToNull', which returns NULL instead
  the date, and 'round', which rounds the date to the nearest closest value
  which is '0001-01-01'.

- Fixed ServerPreparedStatement to read prepared statement metadata off
  the wire, even though it's currently a placeholder instead of using
  MysqlIO.clearInputStream() which didn't work at various times because
  data wasn't available to read from the server yet. This fixes sporadic
  errors users were having with ServerPreparedStatements throwing
  ArrayIndexOutOfBoundExceptions.

- Use com.mysql.jdbc.Message's classloader when loading resource bundle,
  should fix sporadic issues when the caller's classloader can't locate
  the resource bundle.

07-07-04 - Version 3.1.3-beta

- Mangle output parameter names for CallableStatements so they will not clash with user variable names.

- Added support for INOUT parameters in CallableStatements.

- Fix for BUG#4119 [http://bugs.mysql.com/4119], null bitmask sent for serv statements was incorrect.

- Use SQL Standard SQL states by default, unless 'useSqlStateCodes' property is set to 'false'.

- Added packet debuging code (see the 'enablePacketDebug' property documentation).

- Added constants for MySQL error numbers (publicly-accessible, see com.mysql.jdbc.MysqlErrorNumbers), and the ability to generate the mappings of vendor error codes to SQLStates that the driver uses (for documentation purposes).

- Externalized more messages (on-going effort).

- Fix for BUG#4311 [http://bugs.mysql.com/4311] - Error in retrieval of med prepared statements and binary protocol.

- Support new timezone variables in MySQL-4.1.3 when 'useTimezone=true'

- Support for unsigned numerics as return types from prepared statements. This also causes a change in ResultSet.getObject() for the 'bigint unsign type, which used to return BigDecimal instances, it now returns instances of java.lang.BigInteger.

06-09-04 - Version 3.1.2-alpha

- Fixed stored procedure parameter parsing info when size was specified for a parameter (i.e. char(), varchar()).

- Enabled callable statement caching via 'cacheCallableStmts' property.

- Fixed case when no output parameters specified for a stored procedure caused a bogus query to be issued to retrieve out parameters, leading to a syntax error from the server.

- Fixed case when no parameters could cause a NullPointerException in CallableStatement.setOutputParameters().

- Removed wrapping of exceptions in MysqlIO.changeUser().

- Fixed sending of split packets for large queries, enabled nio ability to send large packets as well.

- Added .toString() functionality to ServerPreparedStatement, which should help if you're trying to debug a query that is a prepared statement (it shows SQL as the server would process).

- Added 'gatherPerformanceMetrics' property, along with properties to control when/where this info gets logged (see docs for more info).

- ServerPreparedStatements weren't actually de-allocating server-side resources when .close() was called.

- Added 'logSlowQueries' property, along with property 'slowQueriesThresholdMillis' to control when a query should be considered 'slow'.

- Correctly map output parameters to position given in

```
      prepareCall() vs. order implied during registerOutParameter() -
      fixes BUG#3146 [http://bugs.mysql.com/3146].

    - Correctly detect initial character set for servers >= 4.1.0

    - Cleaned up detection of server properties.

    - Support placeholder for parameter metadata for server >= 4.1.2

    - Fix for BUG#3539 [http://bugs.mysql.com/3539] getProcedures() does not re
      result set

    - Fix for BUG#3540 [http://bugs.mysql.com/3540] getProcedureColumns() doesn
      for procedure name

    - Fixed BUG#3520 [http://bugs.mysql.com/3520] -- DBMD.getSQLStateType() retu

    - Added 'connectionCollation' property to cause driver to issue
      'set collation_connection=...' query on connection init if default
      collation for given charset is not appropriate.

    - Fixed DatabaseMetaData.getProcedures() when run on MySQL-5.0.0 (output of
    'show procedure status' changed between 5.0.1 and 5.0.0.

    - Fixed BUG#3804 [http://bugs.mysql.com/3804] -- getWarnings() returns SQLWa

    - Don't enable server-side prepared statements for server version 5.0.0 or 5
    as they aren't compatible with the '4.1.2+' style that the driver uses (the
    expects information to come back that isn't there, so it hangs).

02-14-04 - Version 3.1.1-alpha

    - Fixed bug with UpdatableResultSets not using client-side
    prepared statements.

    - Fixed character encoding issues when converting bytes to
      ASCII when MySQL doesn't provide the character set, and
      the JVM is set to a multi-byte encoding (usually affecting
      retrieval of numeric values).

    - Unpack 'unknown' data types from server prepared statements
      as Strings.

    - Implemented long data (Blobs, Clobs, InputStreams, Readers)
      for server prepared statements.

    - Implemented Statement.getWarnings() for MySQL-4.1 and newer
      (using 'SHOW WARNINGS').

    - Default result set type changed to TYPE_FORWARD_ONLY
      (JDBC compliance).

    - Centralized setting of result set type and concurrency.

    - Re-factored how connection properties are set and exposed
      as DriverPropertyInfo as well as Connection and DataSource
      properties.

    - Support for NIO. Use 'useNIO=true' on platforms that support
      NIO.

    - Support for SAVEPOINTs (MySQL >= 4.0.14 or 4.1.1).

    - Support for mysql_change_user()...See the changeUser() method
      in com.mysql.jdbc.Connection.

    - Reduced number of methods called in average query to be more
      efficient.

    - Prepared Statements will be re-prepared on auto-reconnect. Any errors
```

```
  encountered are postponed until first attempt to re-execute the
  re-prepared statement.

- Ensure that warnings are cleared before executing queries
  on prepared statements, as-per JDBC spec (now that we support
  warnings).

- Support 'old' profileSql capitalization in ConnectionProperties.
  This property is deprecated, you should use 'profileSQL' if possible.

- Optimized Buffer.readLenByteArray() to return shared empty byte array
  when length is 0.

- Allow contents of PreparedStatement.setBlob() to be retained
  between calls to .execute*().

- Deal with 0-length tokens in EscapeProcessor (caused by callable
  statement escape syntax).

- Check for closed connection on delete/update/insert row operations in
  UpdatableResultSet.

- Fix support for table aliases when checking for all primary keys in
  UpdatableResultSet.

- Removed useFastDates connection property.

- Correctly initialize datasource properties from JNDI Refs, including
  explicitly specified URLs.

- DatabaseMetaData now reports supportsStoredProcedures() for
  MySQL versions >= 5.0.0

- Fixed stack overflow in Connection.prepareCall() (bad merge).

- Fixed IllegalAccessError to Calendar.getTimeInMillis() in DateTimeValue
  (for JDK < 1.4).

- Fix for BUG#1673 [http://bugs.mysql.com/1673], where DatabaseMetaData.get
  returning correct column ordinal info for non '%' column name patterns.

- Merged fix of datatype mapping from MySQL type 'FLOAT' to
  java.sql.Types.REAL from 3.0 branch.

- Detect collation of column for RSMD.isCaseSensitive().

- Fixed sending of queries > 16M.

- Added named and indexed input/output parameter support to CallableStateme
  MySQL-5.0.x or newer.

- Fixed NullPointerException in ServerPreparedStatement.setTimestamp(),
  as well as year and month descrepencies in
  ServerPreparedStatement.setTimestamp(), setDate().

- Added ability to have multiple database/JVM targets for compliance
  and regression/unit tests in build.xml.

- Fixed NPE and year/month bad conversions when accessing some
  datetime functionality in ServerPreparedStatements and their
  resultant result sets.

- Display where/why a connection was implicitly closed (to
  aid debugging).

- CommunicationsException implemented, that tries to determine
  why communications was lost with a server, and displays
  possible reasons when .getMessage() is called.

- Fixed BUG#2359 [http://bugs.mysql.com/2359], NULL values for numeric type
```

```
      encoded result sets causing NullPointerExceptions.

    - Implemented Connection.prepareCall(), and DatabaseMetaData.
      getProcedures() and getProcedureColumns().

    - Reset 'long binary' parameters in ServerPreparedStatement when
      clearParameters() is called, by sending COM_RESET_STMT to the
      server.

    - Merged prepared statement caching, and .getMetaData() support
      from 3.0 branch.

    - Fixed off-by-1900 error in some cases for
      years in TimeUtil.fastDate/TimeCreate() when unpacking results
      from server-side prepared statements.

    - Fixed BUG#2502 [http://bugs.mysql.com/2502] -- charset conversion issue i

    - Implemented multiple result sets returned from a statement
      or stored procedure.

    - Fixed BUG#2606 [http://bugs.mysql.com/2606] -- Server side prepared state
      datatype 'YEAR' correctly.

    - Enabled streaming of result sets from server-side prepared
      statements.

    - Fixed BUG#2623 [http://bugs.mysql.com/2623] -- Class-cast exception when
      scrolling result sets and server-side prepared statements.

    - Merged unbuffered input code from 3.0.

    - Fixed ConnectionProperties that weren't properly exposed
      via accessors, cleaned up ConnectionProperties code.

    - Fixed BUG#2671 [http://bugs.mysql.com/2671], NULL fields not being encode
      all cases in server side prepared statements.

    - Fixed rare buffer underflow when writing numbers into buffers
      for sending prepared statement execution requests.

    - Use DocBook version of docs for shipped versions of drivers.

02-18-03 - Version 3.1.0-alpha

    - Added 'requireSSL' property.

    - Added 'useServerPrepStmts' property (default 'false'). The
      driver will use server-side prepared statements when the
      server version supports them (4.1 and newer) when this
      property is set to 'true'. It is currently set to 'false'
      by default until all bind/fetch functionality has been
      implemented. Currently only DML prepared statements are
      implemented for 4.1 server-side prepared statements.

    - Track open Statements, close all when Connection.close()
      is called (JDBC compliance).

06-23-05 - Version 3.0.17-ga

    - Fixed BUG#5874 [http://bugs.mysql.com/5874], Timestamp/Time conversion go
      when useTimeZone='true' and server timezone differs from client timezone.

    - Fixed BUG#7081 [http://bugs.mysql.com/7081], DatabaseMetaData.getIndexInf
      parameter.

    - Support new protocol type 'MYSQL_TYPE_VARCHAR'.

    - Added 'useOldUTF8Behavoior' configuration property, which causes
      JDBC driver to act like it did with MySQL-4.0.x and earlier when
```

```
      the character encoding is 'utf-8' when connected to MySQL-4.1 or
      newer.

    - Fixed BUG#7316 [http://bugs.mysql.com/7316] - Statements created from a p
      returning physical connection instead of logical connection when
      getConnection() was called.

    - Fixed BUG#7033 [http://bugs.mysql.com/7033] - PreparedStatements don't en
      multi-byte) character sets correctly in static SQL strings.

    - Fixed BUG#6966 [http://bugs.mysql.com/6966], connections starting up fail
      never retry master.

    - Fixed BUG#7061 [http://bugs.mysql.com/7061], PreparedStatement.fixDecimal
      '+', making number unparseable by MySQL server.

    - Fixed BUG#7686 [http://bugs.mysql.com/7686], Timestamp key column data ne
      UpdatableResultSet.refreshRow().

    - Backported SQLState codes mapping from Connector/J 3.1, enable with
      'useSqlStateCodes=true' as a connection property, it defaults to
      'false' in this release, so that we don't break legacy applications (it
      defaults to 'true' starting with Connector/J 3.1).

    - Fixed BUG#7601 [http://bugs.mysql.com/7601], PreparedStatement.fixDecimal
      '+', making number unparseable by MySQL server.

    - Escape sequence {fn convert(..., type)} now supports ODBC-style types
      that are prepended by 'SQL_'.

    - Fixed duplicated code in configureClientCharset() that prevented
      useOldUTF8Behavior=true from working properly.

    - Handle streaming result sets with > 2 billion rows properly by fixing
      wraparound of row number counter.

    - Fixed BUG#7607 [http://bugs.mysql.com/7607] - MS932, SHIFT_JIS and Window
      aliases for sjis.

    - Fixed BUG#6549 [http://bugs.mysql.com/6549] (while fixing #7607), adding
      sjis.

    - Fixed BUG#8064 [http://bugs.mysql.com/8064], which requires hex escaping
      multi-byte charsets with prepared statements.

    - Fixed BUG#8812 [http://bugs.mysql.com/8812], NON_UNIQUE column from DBMD.
      inverted value.

    - Workaround for server BUG#9098 [http://bugs.mysql.com/9098] - default val
      DATE/TIME/TIMESTAMP/TIMESTAMP columns can't be distinguished from
      'string' values, so UpdatableResultSet.moveToInsertRow() generates
      bad SQL for inserting default values.

    - Fixed BUG#8629 [http://bugs.mysql.com/8629] - 'EUCKR' charset is sent as
      MySQL-4.1 and newer doesn't understand.

    - DatabaseMetaData.supportsSelectForUpdate() returns correct value based
      on server version.

    - Use hex escapes for PreparedStatement.setBytes() for double-byte charsets
      including 'aliases' Windows-31J, CP934, MS932.

    - Added support for the "EUC_JP_Solaris" character encoding, which maps
      to a MySQL encoding of "eucjpms" (backported from 3.1 branch). This only
      works on servers that support eucjpms, namely 5.0.3 or later.

11-15-04 - Version 3.0.16-ga

    - Re-issue character set configuration commands when re-using pooled
      connections and/or Connection.changeUser() when connected to MySQL-4.1
```

```
      or newer.

    - Fixed ResultSetMetaData.isReadOnly() to detect non-writable columns
      when connected to MySQL-4.1 or newer, based on existence of 'original'
      table and column names.

    - Fixed BUG#5664 [http://bugs.mysql.com/5664], ResultSet.updateByte() when
      throws ArrayOutOfBoundsException.

    - Fixed DatabaseMetaData.getTypes() returning incorrect (i.e. non-negative)
      scale for the 'NUMERIC' type.

    - Fixed BUG#6198 [http://bugs.mysql.com/6198], off-by-one bug in Buffer.rea

    - Made TINYINT(1) -> BIT/Boolean conversion configurable via 'tinyInt1isBit
      property (default 'true' to be JDBC compliant out of the box).

    - Only set 'character_set_results' during connection establishment if
      server version >= 4.1.1.

    - Fixed regression where useUnbufferedInput was defaulting to 'false'.

    - Fixed BUG#6231 [http://bugs.mysql.com/6231], ResultSet.getTimestamp() on
      fails.

09-04-04 - Version 3.0.15-production

    - Fixed BUG#4010 [http://bugs.mysql.com/4010] - StringUtils.escapeEasternUn
      broken for GBK

    - Fixed BUG#4334 [http://bugs.mysql.com/4334] - Failover for autoReconnect
      hosts, and not retrying all hosts. (WARN: This required a change to
      the SocketFactory connect() method signature, which is now

       public Socket connect(String host, int portNumber, Properties props)

      therefore any third-party socket factories will have to be changed
      to support this signature.

    - Logical connections created by MysqlConnectionPoolDataSource will
      now issue a rollback() when they are closed and sent back to the pool.
      If your application server/connection pool already does this for you, you
      can set the 'rollbackOnPooledClose' property to false to avoid the
      overhead of an extra rollback().

    - Removed redundant calls to checkRowPos() in ResultSet.

    - Fixed BUG#4742 [http://bugs.mysql.com/4742], 'DOUBLE' mapped twice in DBM

    - Added FLOSS license exemption.

    - Fixed BUG#4808 [http://bugs.mysql.com/4808], calling .close() twice on a

    - Fixed BUG#4138 [http://bugs.mysql.com/4138] and BUG#4860 [http://bugs.mys
      type for unsigned columns. This affects type mappings for all numeric
      types in the RSMD.getColumnType() and RSMD.getColumnTypeNames() methods
      as well, to ensure that 'like' types from DBMD.getColumns() match up
      with what RSMD.getColumnType() and getColumnTypeNames() return.

    - 'Production' - 'GA' in naming scheme of distributions.

    - Fix for BUG#4880 [http://bugs.mysql.com/4880], RSMD.getPrecision() return
      (should return max length in chars for non-binary types, max length
      in bytes for binary types). This fix also fixes mapping of
      RSMD.getColumnType() and RSMD.getColumnTypeName() for the BLOB types base
      on the length sent from the server (the server doesn't distinguish betwee
      TINYBLOB, BLOB, MEDIUMBLOB or LONGBLOB at the network protocol level).

    - Fixed BUG#5022 [http://bugs.mysql.com/5022] - ResultSet should release Fi
```

```
    - Fixed BUG#5069 [http://bugs.mysql.com/5069] -- ResultSet.getMetaData() sh
      incorrectly-initialized metadata if the result set has been closed, but
      should instead throw an SQLException. Also fixed for getRow() and
      getWarnings() and traversal methods by calling checkClosed() before
      operating on instance-level fields that are nullified during .close().

    - Parse new timezone variables from 4.1.x servers.

    - Use _binary introducer for PreparedStatement.setBytes() and
      set*Stream() when connected to MySQL-4.1.x or newer to avoid
      misinterpretation during character conversion.

05-28-04 - Version 3.0.14-production

    - Fixed URL parsing error

05-27-04 - Version 3.0.13-production

    - Fixed BUG#3848 [http://bugs.mysql.com/3848] - Using a MySQLDatasource wit

    - Fixed BUG#3920 [http://bugs.mysql.com/3920] - "No Database Selected" when
    MysqlConnectionPoolDataSource.

    - Fixed BUG#3873 [http://bugs.mysql.com/3873] - PreparedStatement.getGenera
    1 result for batched insertions

05-18-04 - Version 3.0.12-production

    - Add unsigned attribute to DatabaseMetaData.getColumns() output
    in the TYPE_NAME column.

    - Added 'failOverReadOnly' property, to allow end-user to configure
    state of connection (read-only/writable) when failed over.

    - Backported 'change user' and 'reset server state' functionality
      from 3.1 branch, to allow clients of MysqlConnectionPoolDataSource
      to reset server state on getConnection() on a pooled connection.

    - Don't escape SJIS/GBK/BIG5 when using MySQL-4.1 or newer.

    - Allow 'url' parameter for MysqlDataSource and MysqlConnectionPool
      DataSource so that passing of other properties is possible from
      inside appservers.

    - Map duplicate key and foreign key errors to SQLState of
      '23000'.

    - Backport documentation tooling from 3.1 branch.

    - Return creating statement for ResultSets created by
      getGeneratedKeys() (BUG#2957 [http://bugs.mysql.com/2957])

    - Allow java.util.Date to be sent in as parameter to
      PreparedStatement.setObject(), converting it to a Timestamp
      to maintain full precision (BUG#3103 [http://bugs.mysql.com/3103]).

    - Don't truncate BLOBs/CLOBs when using setBytes() and/or
      setBinary/CharacterStream() (BUG#2670 [http://bugs.mysql.com/2670]).

    - Dynamically configure character set mappings for field-level
      character sets on MySQL-4.1.0 and newer using 'SHOW COLLATION'
      when connecting.

    - Map 'binary' character set to 'US-ASCII' to support DATETIME
      charset recognition for servers >= 4.1.2

    - Use 'SET character_set_results" during initialization to allow any
      charset to be returned to the driver for result sets.

    - Use charsetnr returned during connect to encode queries before
```

```
      issuing 'SET NAMES' on MySQL >= 4.1.0.

    - Add helper methods to ResultSetMetaData (getColumnCharacterEncoding()
      and getColumnCharacterSet()) to allow end-users to see what charset
      the driver thinks it should be using for the column.

    - Only set character_set_results for MySQL >= 4.1.0.

    - Fixed BUG#3511 [http://bugs.mysql.com/3511], StringUtils.escapeSJISByteSt
      eastern double-byte charsets correctly.

    - Renamed StringUtils.escapeSJISByteStream() to more appropriate
      escapeEasternUnicodeByteStream().

    - Fixed BUG#3554 [http://bugs.mysql.com/3554] - Not specifying database in
      exception.

    - Auto-convert MySQL encoding names to Java encoding names if used
      for characterEncoding property.

    - Added encoding names that are recognized on some JVMs to fix case
      where they were reverse-mapped to MySQL encoding names incorrectly.

    - Use junit.textui.TestRunner for all unit tests (to allow them to be
      run from the command line outside of Ant or Eclipse).

    - Fixed BUG#3557 [http://bugs.mysql.com/3557] - UpdatableResultSet not pick
      for moveToInsertRow().

    - Fixed BUG#3570 [http://bugs.mysql.com/3570] - inconsistent reporting of da
      still doesn't return all types for *BLOBs *TEXT correctly, so the
      driver won't return those correctly.

    - Fixed BUG#3520 [http://bugs.mysql.com/3520] -- DBMD.getSQLStateType() retu

    - Fixed regression in PreparedStatement.setString() and eastern character
      encodings.

    - Made StringRegressionTest 4.1-unicode aware.

02-19-04 - Version 3.0.11-stable

    - Trigger a 'SET NAMES utf8' when encoding is forced to 'utf8' _or_
    'utf-8' via the 'characterEncoding' property. Previously, only the
    Java-style encoding name of 'utf-8' would trigger this.

    - AutoReconnect time was growing faster than exponentially (BUG#2447 [http:/

    - Fixed failover always going to last host in list (BUG#2578 [http://bugs.my

    - Added 'useUnbufferedInput' parameter, and now use it by default
      (due to JVM issue
      http://developer.java.sun.com/developer/bugParade/bugs/4401235.html)

    - Detect 'on/off' or '1','2','3' form of lower_case_table_names on
      server.

    - Return 'java.lang.Integer' for TINYINT and SMALLINT types from
      ResultSetMetaData.getColumnClassName() (fix for BUG#2852 [http://bugs.mysq

    - Return 'java.lang.Double' for FLOAT type from ResultSetMetaData.
      getColumnClassName() (fix for BUG#2855 [http://bugs.mysql.com/2855]).

    - Return '[B' instead of java.lang.Object for BINARY, VARBINARY and
      LONGVARBINARY types from ResultSetMetaData.getColumnClassName()
      (JDBC compliance).

    - Issue connection events on all instances created from a
      ConnectionPoolDataSource.
```

```
01-13-04 - Version 3.0.10-stable

    - Don't count quoted id's when inside a 'string' in PreparedStatement
      parsing (fix for BUG#1511 [http://bugs.mysql.com/1511]).

    - 'Friendlier' exception message for PacketTooLargeException
       (BUG#1534 [http://bugs.mysql.com/1534]).

    - Backported fix for aliased tables and UpdatableResultSets in
      checkUpdatability() method from 3.1 branch.

    - Fix for ArrayIndexOutOfBounds exception when using Statement.setMaxRows()
      (BUG#1695 [http://bugs.mysql.com/1695]).

    - Fixed BUG#1576 [http://bugs.mysql.com/1576], dealing with large blobs and
      read correctly.

    - Fixed regression of Statement.getGeneratedKeys() and REPLACE statements.

    - Fixed BUG#1630 [http://bugs.mysql.com/1630], subsequent call to ResultSet
      result set is not updatable.

    - Fix for 4.1.1-style auth with no password.

    - Fix for BUG#1731 [http://bugs.mysql.com/1731], Foreign Keys column sequen
      DatabaseMetaData.getImported/Exported/CrossReference().

    - Fix for BUG#1775 [http://bugs.mysql.com/1775] - DatabaseMetaData.getSyste
      bad function 'VResultsSion'.

    - Fix for BUG#1592 [http://bugs.mysql.com/1592] -- cross-database updatable
      are not checked for updatability correctly.

    - DatabaseMetaData.getColumns() should return Types.LONGVARCHAR for
      MySQL LONGTEXT type.

    - ResultSet.getObject() on TINYINT and SMALLINT columns should return
      Java type 'Integer' (BUG#1913 [http://bugs.mysql.com/1913])

    - Added 'alwaysClearStream' connection property, which causes the driver
      to always empty any remaining data on the input stream before
      each query.

    - Added more descriptive error message 'Server Configuration Denies
      Access to DataSource', as well as retrieval of message from server.

    - Autoreconnect code didn't set catalog upon reconnect if it had been
      changed.

    - Implement ResultSet.updateClob().

    - ResultSetMetaData.isCaseSensitive() returned wrong value for CHAR/VARCHAR
      columns.

    - Fix for BUG#1933 [http://bugs.mysql.com/1933] -- Connection property "max

    - Fix for BUG#1925 [http://bugs.mysql.com/1925] -- Statements being created
      DBMD.extractForeignKeyFromCreateTable().

    - Fix for BUG#1914 [http://bugs.mysql.com/1914] -- Support escape sequence

    - Fix for BUG#1958 [http://bugs.mysql.com/1958] -- ArrayIndexOutOfBounds wh
      number of parameters + 1.

    - Fix for BUG#2006 [http://bugs.mysql.com/2006] -- ResultSet.findColumn() s
      column name when there are duplicate column names in SELECT query
      (JDBC-compliance).

    - Removed static synchronization bottleneck from
      PreparedStatement.setTimestamp().
```

```
    - Removed static synchronization bottleneck from instance factory
      method of SingleByteCharsetConverter.

    - Enable caching of the parsing stage of prepared statements via
      the 'cachePrepStmts', 'prepStmtCacheSize' and 'prepStmtCacheSqlLimit'
      properties (disabled by default).

    - Speed up parsing of PreparedStatements, try to use one-pass whenever
      possible.

    - Fixed security exception when used in Applets (applets can't
      read the system property 'file.encoding' which is needed
      for LOAD DATA LOCAL INFILE).

    - Use constants for SQLStates.

    - Map charset 'ko18_ru' to 'ko18r' when connected to MySQL-4.1.0 or
      newer.

    - Ensure that Buffer.writeString() saves room for the \0.

    - Fixed exception 'Unknown character set 'danish' on connect w/ JDK-1.4.0

    - Fixed mappings in SQLError to report deadlocks with SQLStates of '41000'.

    - 'maxRows' property would affect internal statements, so check it for all
      statement creation internal to the driver, and set to 0 when it is not.

10-07-03 - Version 3.0.9-stable

    - Faster date handling code in ResultSet and PreparedStatement (no longer
      uses Date methods that synchronize on static calendars).

    - Fixed test for end of buffer in Buffer.readString().

    - Fixed ResultSet.previous() behavior to move current
      position to before result set when on first row
      of result set (bugs.mysql.com BUG#496 [http://bugs.mysql.com/496])

    - Fixed Statement and PreparedStatement issuing bogus queries
      when setMaxRows() had been used and a LIMIT clause was present
      in the query.

    - Fixed BUG#661 [http://bugs.mysql.com/661] - refreshRow didn't work when p
      contained values that needed to be escaped (they ended up being
      doubly-escaped).

    - Support InnoDB contraint names when extracting foreign key info
      in DatabaseMetaData BUG#517 [http://bugs.mysql.com/517] and BUG#664 [http
      (impl. ideas from Parwinder Sekhon)

    - Backported 4.1 protocol changes from 3.1 branch (server-side SQL
      states, new field info, larger client capability flags,
      connect-with-database, and so forth).

    - Fix UpdatableResultSet to return values for getXXX() when on
      insert row (BUG#675 [http://bugs.mysql.com/675]).

    - The insertRow in an UpdatableResultSet is now loaded with
      the default column values when moveToInsertRow() is called
      (BUG#688 [http://bugs.mysql.com/688])

    - DatabaseMetaData.getColumns() wasn't returning NULL for
      default values that are specified as NULL.

    - Change default statement type/concurrency to TYPE_FORWARD_ONLY
      and CONCUR_READ_ONLY (spec compliance).

    - Don't try and reset isolation level on reconnect if MySQL doesn't
```

support them.

- Don't wrap SQLExceptions in RowDataDynamic.

- Don't change timestamp TZ twice if useTimezone==true (BUG#774 [http://bug

- Fixed regression in large split-packet handling (BUG#848 [http://bugs.mys

- Better diagnostic error messages in exceptions for 'streaming' result sets.

- Issue exception on ResultSet.getXXX() on empty result set (wasn't caught in some cases).

- Don't hide messages from exceptions thrown in I/O layers.

- Don't fire connection closed events when closing pooled connections, or on PooledConnection.getConnection() with already open connections (BUG#88

- Clip +/- INF (to smallest and largest representative values for the type MySQL) and NaN (to 0) for setDouble/setFloat(), and issue a warning on th statement when the server does not support +/- INF or NaN.

- Fix for BUG#879 [http://bugs.mysql.com/879], double-escaping of '\' when appears in non-escaped input.

- When emptying input stream of unused rows for 'streaming' result sets, have the current thread yield() every 100 rows in order to not monopolize CPU time.

- Fixed BUG#1099 [http://bugs.mysql.com/1099], DatabaseMetaData.getColumns(keyword 'set' in character columns.

- Fixed deadlock issue with Statement.setMaxRows().

- Fixed CLOB.truncate(), BUG#1130 [http://bugs.mysql.com/1130]

- Optimized CLOB.setChracterStream(), BUG#1131 [http://bugs.mysql.com/1131]

- Made databaseName, portNumber and serverName optional parameters for MysqlDataSourceFactory (BUG#1246 [http://bugs.mysql.com/1246])

- Fix for BUG#1247 [http://bugs.mysql.com/1247] -- ResultSet.get/setString

- Backported auth. changes for 4.1.1 and newer from 3.1 branch.

- Added com.mysql.jdbc.util.BaseBugReport to help creation of testcases for bug reports.

- Added property to 'clobber' streaming results, by setting the 'clobberStreamingResults' property to 'true' (the default is 'false'). This will cause a 'streaming' ResultSet to be automatically closed, and any oustanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.

05-23-03 - Version 3.0.8-stable

- Allow bogus URLs in Driver.getPropertyInfo().

- Return list of generated keys when using multi-value INSERTS with Statement.getGeneratedKeys().

- Use JVM charset with filenames and 'LOAD DATA [LOCAL] INFILE'

- Fix infinite loop with Connection.cleanup().

- Changed Ant target 'compile-core' to 'compile-driver', and made testsuite compilation a separate target.

```
    - Fixed result set not getting set for Statement.executeUpdate(),
      which affected getGeneratedKeys() and getUpdateCount() in
      some cases.

    - Unicode character 0xFFFF in a string would cause the driver to
      throw an ArrayOutOfBoundsException (Bug #378 [http://bugs.mysql.com/378])

    - Return correct amount of generated keys when using 'REPLACE'
      statements.

    - Fix problem detecting server character set in some cases.

    - Fix row data decoding error when using _very_ large packets.

    - Optimized row data decoding.

    - Issue exception when operating on an already-closed
      prepared statement.

    - Fixed SJIS encoding bug, thanks to Naoto Sato.

    - Optimized usage of EscapeProcessor.

    - Allow multiple calls to Statement.close()

04-08-03 - Version 3.0.7-stable

    - Fixed MysqlPooledConnection.close() calling wrong event type.

    - Fixed StringIndexOutOfBoundsException in PreparedStatement.
      setClob().

    - 4.1 Column Metadata fixes

    - Remove synchronization from Driver.connect() and
      Driver.acceptsUrl().

    - IOExceptions during a transaction now cause the Connection to
      be closed.

    - Fixed missing conversion for 'YEAR' type in ResultSetMetaData.
      getColumnTypeName().

    - Don't pick up indexes that start with 'pri' as primary keys
      for DBMD.getPrimaryKeys().

    - Throw SQLExceptions when trying to do operations on a forcefully
      closed Connection (i.e. when a communication link failure occurs).

    - You can now toggle profiling on/off using
      Connection.setProfileSql(boolean).

    - Fixed charset issues with database metadata (charset was not
      getting set correctly).

    - Updatable ResultSets can now be created for aliased tables/columns
      when connected to MySQL-4.1 or newer.

    - Fixed 'LOAD DATA LOCAL INFILE' bug when file > max_allowed_packet.

    - Fixed escaping of 0x5c ('\') character for GBK and Big5 charsets.

    - Fixed ResultSet.getTimestamp() when underlying field is of type DATE.

    - Ensure that packet size from alignPacketSize() does not
      exceed MAX_ALLOWED_PACKET (JVM bug)

    - Don't reset Connection.isReadOnly() when autoReconnecting.

02-18-03 - Version 3.0.6-stable
```

```
    - Fixed ResultSetMetaData to return "" when catalog not known.
      Fixes NullPointerExceptions with Sun's CachedRowSet.

    - Fixed DBMD.getTypeInfo() and DBMD.getColumns() returning
      different value for precision in TEXT/BLOB types.

    - Allow ignoring of warning for 'non transactional tables' during
      rollback (compliance/usability) by setting 'ignoreNonTxTables'
      property to 'true'.

    - Fixed SQLExceptions getting swallowed on initial connect.

    - Fixed Statement.setMaxRows() to stop sending 'LIMIT' type queries
      when not needed (performance)

    - Clean up Statement query/method mismatch tests (i.e. INSERT not
      allowed with .executeQuery()).

    - More checks added in ResultSet traversal method to catch
      when in closed state.

    - Fixed ResultSetMetaData.isWritable() to return correct value.

    - Add 'window' of different NULL sorting behavior to
      DBMD.nullsAreSortedAtStart (4.0.2 to 4.0.10, true, otherwise,
      no).

    - Implemented Blob.setBytes(). You still need to pass the
      resultant Blob back into an updatable ResultSet or
      PreparedStatement to persist the changes, as MySQL does
      not support 'locators'.

    - Backported 4.1 charset field info changes from Connector/J 3.1

01-22-03 - Version 3.0.5-gamma

    - Fixed Buffer.fastSkipLenString() causing ArrayIndexOutOfBounds
      exceptions with some queries when unpacking fields.

    - Implemented an empty TypeMap for Connection.getTypeMap() so that
      some third-party apps work with MySQL (IBM WebSphere 5.0 Connection
      pool).

    - Added missing LONGTEXT type to DBMD.getColumns().

    - Retrieve TX_ISOLATION from database for
      Connection.getTransactionIsolation() when the MySQL version
      supports it, instead of an instance variable.

    - Quote table names in DatabaseMetaData.getColumns(),
      getPrimaryKeys(), getIndexInfo(), getBestRowIdentifier()

    - Greatly reduce memory required for setBinaryStream() in
      PreparedStatements.

    - Fixed ResultSet.isBeforeFirst() for empty result sets.

    - Added update options for foreign key metadata.

01-06-03 - Version 3.0.4-gamma

    - Added quoted identifiers to database names for
      Connection.setCatalog.

    - Added support for quoted identifiers in PreparedStatement
      parser.

    - Streamlined character conversion and byte[] handling in
```

```
      PreparedStatements for setByte().

    - Reduce memory footprint of PreparedStatements by sharing
      outbound packet with MysqlIO.

    - Added 'strictUpdates' property to allow control of amount
      of checking for 'correctness' of updatable result sets. Set this
      to 'false' if you want faster updatable result sets and you know
      that you create them from SELECTs on tables with primary keys and
      that you have selected all primary keys in your query.

    - Added support for 4.0.8-style large packets.

    - Fixed PreparedStatement.executeBatch() parameter overwriting.

12-17-02 - Version 3.0.3-dev

    - Changed charsToByte in SingleByteCharConverter to be non-static

    - Changed SingleByteCharConverter to use lazy initialization of each
      converter.

    - Fixed charset handling in Fields.java

    - Implemented Connection.nativeSQL()

    - More robust escape tokenizer -- recognize '--' comments, and allow
      nested escape sequences (see testsuite.EscapeProcessingTest)

    - DBMD.getImported/ExportedKeys() now handles multiple foreign keys
      per table.

    - Fixed ResultSetMetaData.getPrecision() returning incorrect values
      for some floating point types.

    - Fixed ResultSetMetaData.getColumnTypeName() returning BLOB for
      TEXT and TEXT for BLOB types.

    - Fixed Buffer.isLastDataPacket() for 4.1 and newer servers.

    - Added CLIENT_LONG_FLAG to be able to get more column flags
      (isAutoIncrement() being the most important)

    - Because of above, implemented ResultSetMetaData.isAutoIncrement()
      to use Field.isAutoIncrement().

    - Honor 'lower_case_table_names' when enabled in the server when
      doing table name comparisons in DatabaseMetaData methods.

    - Some MySQL-4.1 protocol support (extended field info from selects)

    - Use non-aliased table/column names and database names to fullly
      qualify tables and columns in UpdatableResultSet (requires
      MySQL-4.1 or newer)

    - Allow user to alter behavior of Statement/
      PreparedStatement.executeBatch() via 'continueBatchOnError' property
      (defaults to 'true').

    - Check for connection closed in more Connection methods
      (createStatement, prepareStatement, setTransactionIsolation,
      setAutoCommit).

    - More robust implementation of updatable result sets. Checks that
      _all_ primary keys of the table have been selected.

    - 'LOAD DATA LOCAL INFILE ...' now works, if your server is configured
      to allow it. Can be turned off with the 'allowLoadLocalInfile'
      property (see the README).
```

```
    - Substitute '?' for unknown character conversions in single-byte
      character sets instead of '\0'.

    - NamedPipeSocketFactory now works (only intended for Windows), see
      README for instructions.

11-08-02 - Version 3.0.2-dev

    - Fixed issue with updatable result sets and PreparedStatements not
      working

    - Fixed ResultSet.setFetchDirection(FETCH_UNKNOWN)

    - Fixed issue when calling Statement.setFetchSize() when using
      arbitrary values

    - Fixed incorrect conversion in ResultSet.getLong()

    - Implemented ResultSet.updateBlob().

    - Removed duplicate code from UpdatableResultSet (it can be inherited
      from ResultSet, the extra code for each method to handle updatability
      I thought might someday be necessary has not been needed).

    - Fixed "UnsupportedEncodingException" thrown when "forcing" a
      character encoding via properties.

    - Fixed various non-ASCII character encoding issues.

    - Added driver property 'useHostsInPrivileges'. Defaults to true.
      Affects whether or not '@hostname' will be used in
      DBMD.getColumn/TablePrivileges.

    - All DBMD result set columns describing schemas now return NULL
      to be more compliant with the behavior of other JDBC drivers
      for other database systems (MySQL does not support schemas).

    - Added SSL support. See README for information on how to use it.

    - Properly restore connection properties when autoReconnecting
      or failing-over, including autoCommit state, and isolation level.

    - Use 'SHOW CREATE TABLE' when possible for determining foreign key
      information for DatabaseMetaData...also allows cascade options for
      DELETE information to be returned

    - Escape 0x5c character in strings for the SJIS charset.

    - Fixed start position off-by-1 error in Clob.getSubString()

    - Implemented Clob.truncate()

    - Implemented Clob.setString()

    - Implemented Clob.setAsciiStream()

    - Implemented Clob.setCharacterStream()

    - Added com.mysql.jdbc.MiniAdmin class, which allows you to send
      'shutdown' command to MySQL server...Intended to be used when 'embedding'
      Java and MySQL server together in an end-user application.

    - Added 'connectTimeout' parameter that allows users of JDK-1.4 and newer
      to specify a maxium time to wait to establish a connection.

    - Failover and autoReconnect only work when the connection is in a
      autoCommit(false) state, in order to stay transaction safe

    - Added 'queriesBeforeRetryMaster' property that specifies how many
      queries to issue when failed over before attempting to reconnect
```

```
      to the master (defaults to 50)

    - Fixed DBMD.supportsResultSetConcurrency() so that it returns true
      for ResultSet.TYPE_SCROLL_INSENSITIVE and ResultSet.CONCUR_READ_ONLY or
      ResultSet.CONCUR_UPDATABLE

    - Fixed ResultSet.isLast() for empty result sets (should return false).

    - PreparedStatement now honors stream lengths in setBinary/Ascii/Character
      Stream() unless you set the connection property
      'useStreamLengthsInPrepStmts' to 'false'.

    - Removed some not-needed temporary object creation by using Strings
      smarter in EscapeProcessor, Connection and DatabaseMetaData classes.

09-21-02 - Version 3.0.1-dev

    - Fixed ResultSet.getRow() off-by-one bug.

    - Fixed RowDataStatic.getAt() off-by-one bug.

    - Added limited Clob functionality (ResultSet.getClob(),
      PreparedStatemtent.setClob(),
      PreparedStatement.setObject(Clob).

    - Added socketTimeout parameter to URL.

    - Connection.isClosed() no longer "pings" the server.

    - Connection.close() issues rollback() when getAutoCommit() == false

    - Added "paranoid" parameter...sanitizes error messages removing
      "sensitive" information from them (such as hostnames, ports, or
      usernames), as well as clearing "sensitive" data structures
      when possible.

    - Fixed ResultSetMetaData.isSigned() for TINYINT and BIGINT.

    - Charsets now automatically detected. Optimized code for single-byte
      character set conversion.

    - Implemented ResultSet.getCharacterStream()

    - Added "LOCAL TEMPORARY" to table types in DatabaseMetaData.getTableTypes(

    - Massive code clean-up to follow Java coding conventions (the time had com

07-31-02 - Version 3.0.0-dev

    - !!! LICENSE CHANGE !!! The driver is now GPL. If you need
      non-GPL licenses, please contact me <mark@mysql.com>

    - JDBC-3.0 functionality including
      Statement/PreparedStatement.getGeneratedKeys() and
      ResultSet.getURL()

    - Performance enchancements - driver is now 50-100% faster
      in most situations, and creates fewer temporary objects

    - Repackaging...new driver name is "com.mysql.jdbc.Driver",
      old name still works, though (the driver is now provided
      by MySQL-AB)

    - Better checking for closed connections in Statement
      and PreparedStatement.

    - Support for streaming (row-by-row) result sets (see README)
      Thanks to Doron.
```

```
    - Support for large packets (new addition to MySQL-4.0 protocol),
      see README for more information.

    - JDBC Compliance -- Passes all tests besides stored procedure tests

    - Fix and sort primary key names in DBMetaData (SF bugs 582086 and 582086)

    - Float types now reported as java.sql.Types.FLOAT (SF bug 579573)

    - ResultSet.getTimestamp() now works for DATE types (SF bug 559134)

    - ResultSet.getDate/Time/Timestamp now recognizes all forms of invalid
      values that have been set to all zeroes by MySQL (SF bug 586058)

    - Testsuite now uses Junit (which you can get from www.junit.org)

    - The driver now only works with JDK-1.2 or newer.

    - Added multi-host failover support (see README)

    - General source-code cleanup.

    - Overall speed improvements via controlling transient object
      creation in MysqlIO class when reading packets

    - Performance improvements in  string handling and field
      metadata creation (lazily instantiated) contributed by
      Alex Twisleton-Wykeham-Fiennes

05-16-02 - Version 2.0.14

    - More code cleanup

    - PreparedStatement now releases resources on .close() (SF bug 553268)

    - Quoted identifiers not used if server version does not support them. Also
      if server started with --ansi or --sql-mode=ANSI_QUOTES then '"' will be
      used as an identifier quote, otherwise '`' will be used.

    - ResultSet.getDouble() now uses code built into JDK to be more precise (bu

    - LogicalHandle.isClosed() calls through to physical connection

    - Added SQL profiling (to STDERR). Set "profileSql=true" in your JDBC url.
      See README for more information.

    - Fixed typo for relaxAutoCommit parameter.

04-24-02 - Version 2.0.13

    - More code cleanup.

    - Fixed unicode chars being read incorrectly (SF bug 541088)

    - Faster blob escaping for PrepStmt

    - Added set/getPortNumber() to DataSource(s) (SF bug 548167)

    - Added setURL() to MySQLXADataSource (SF bug 546019)

    - PreparedStatement.toString() fixed (SF bug 534026)

    - ResultSetMetaData.getColumnClassName() now implemented

    - Rudimentary version of Statement.getGeneratedKeys() from JDBC-3.0
      now implemented (you need to be using JDK-1.4 for this to work, I
      believe)
```

```
    - DBMetaData.getIndexInfo() - bad PAGES fixed (SF BUG 542201)

04-07-02 - Version 2.0.12

    - General code cleanup.

    - Added getIdleFor() method to Connection and MysqlLogicalHandle.

    - Relaxed synchronization in all classes, should fix 520615 and 520393.

    - Added getTable/ColumnPrivileges() to DBMD (fixes 484502).

    - Added new types to getTypeInfo(), fixed existing types thanks to
      Al Davis and Kid Kalanon.

    - Added support for BIT types (51870) to PreparedStatement.

    - Fixed getRow() bug (527165) in ResultSet

    - Fixes for ResultSet updatability in PreparedStatement.
    - Fixed timezone off by 1-hour bug in PreparedStatement (538286, 528785).

    - ResultSet: Fixed updatability (values being set to null
      if not updated).

    - DataSources - fixed setUrl bug (511614, 525565),
      wrong datasource class name (532816, 528767)

    - Added identifier quoting to all DatabaseMetaData methods
      that need them (should fix 518108)

    - Added support for YEAR type (533556)

    - ResultSet.insertRow() should now detect auto_increment fields
      in most cases and use that value in the new row. This detection
      will not work in multi-valued keys, however, due to the fact that
      the MySQL protocol does not return this information.

    - ResultSet.refreshRow() implemented.

    - Fixed testsuite.Traversal afterLast() bug, thanks to Igor Lastric.

01-27-02 - Version 2.0.11

    - Fixed missing DELETE_RULE value in
      DBMD.getImported/ExportedKeys() and getCrossReference().

    - Full synchronization of Statement.java.

    - More changes to fix "Unexpected end of input stream"
      errors when reading BLOBs. This should be the last fix.

01-24-02 - Version 2.0.10

     - Fixed spurious "Unexpected end of input stream" errors in
       MysqlIO (bug 507456).

     - Fixed null-pointer-exceptions when using
       MysqlConnectionPoolDataSource with Websphere 4 (bug 505839).

01-13-02 - Version 2.0.9

     - Ant build was corrupting included jar files, fixed
       (bug 487669).

     - Fixed extra memory allocation in MysqlIO.readPacket()
       (bug 488663).

     - Implementation of DatabaseMetaData.getExported/ImportedKeys() and
       getCrossReference().
```

```
     - Full synchronization on methods modifying instance and class-shared
       references, driver should be entirely thread-safe now (please
       let me know if you have problems)

     - DataSource implementations moved to org.gjt.mm.mysql.jdbc2.optional
       package, and (initial) implementations of PooledConnectionDataSource
       and XADataSource are in place (thanks to Todd Wolff for the
       implementation and testing of PooledConnectionDataSource with
       IBM WebSphere 4).

     - Added detection of network connection being closed when reading packets
       (thanks to Todd Lizambri).

     - Fixed quoting error with escape processor (bug 486265).

     - Report batch update support through DatabaseMetaData (bug 495101).

     - Fixed off-by-one-hour error in PreparedStatement.setTimestamp()
       (bug 491577).

     - Removed concatenation support from driver (the '||' operator),
       as older versions of VisualAge seem to be the only thing that
       use it, and it conflicts with the logical '||' operator. You will
       need to start mysqld with the "--ansi" flag to use the '||'
       operator as concatenation (bug 491680)

     - Fixed casting bug in PreparedStatement (bug 488663).

11-25-01 - Version 2.0.8

     - Batch updates now supported (thanks to some inspiration
       from Daniel Rall).

     - XADataSource/ConnectionPoolDataSource code (experimental)

     - PreparedStatement.setAnyNumericType() now handles positive
       exponents correctly (adds "+" so MySQL can understand it).

     - DatabaseMetaData.getPrimaryKeys() and getBestRowIdentifier()
       are now more robust in identifying primary keys (matches
       regardless of case or abbreviation/full spelling of Primary Key
       in Key_type column).

10-24-01 - Version 2.0.7

     - PreparedStatement.setCharacterStream() now implemented

     - Fixed dangling socket problem when in high availability
       (autoReconnect=true) mode, and finalizer for Connection will
       close any dangling sockets on GC.

     - Fixed ResultSetMetaData.getPrecision() returning one
       less than actual on newer versions of MySQL.

     - ResultSet.getBlob() now returns null if column value
       was null.

     - Character sets read from database if useUnicode=true
       and characterEncoding is not set. (thanks to
       Dmitry Vereshchagin)

     - Initial transaction isolation level read from
       database (if avaialable) (thanks to Dmitry Vereshchagin)

     - Fixed DatabaseMetaData.supportsTransactions(), and
       supportsTransactionIsolationLevel() and getTypeInfo()
       SQL_DATETIME_SUB and SQL_DATA_TYPE fields not being
       readable.
```

```
     - Fixed PreparedStatement generating SQL that would end
       up with syntax errors for some queries.

     - Fixed ResultSet.isAfterLast() always returning false.

     - Fixed timezone issue in PreparedStatement.setTimestamp()
       (thanks to Erik Olofsson)

     - Captialize type names when "captializeTypeNames=true"
       is passed in URL or properties (for WebObjects, thanks
       to Anjo Krank)

     - Updatable result sets now correctly handle NULL
       values in fields.

     - PreparedStatement.setDouble() now uses full-precision
       doubles (reverting a fix made earlier to truncate them).

     - PreparedStatement.setBoolean() will use 1/0 for values
       if your MySQL version is 3.21.23 or higher.

06-16-01 - Version 2.0.6

     - Fixed PreparedStatement parameter checking

     - Fixed case-sensitive column names in ResultSet.java

06-13-01 - Version 2.0.5

     - Fixed ResultSet.getBlob() ArrayIndex out-of-bounds

     - Fixed ResultSetMetaData.getColumnTypeName for TEXT/BLOB

     - Fixed ArrayIndexOutOfBounds when sending large BLOB queries
       (Max size packet was not being set)

     - Added ISOLATION level support to Connection.setIsolationLevel()

     - Fixed NPE on PreparedStatement.executeUpdate() when all columns
       have not been set.

     - Fixed data parsing of TIMESTAMPs with 2-digit years

     - Added Byte to PreparedStatement.setObject()

     - ResultSet.getBoolean() now recognizes '-1' as 'true'

     - ResultSet has +/-Inf/inf support

     - ResultSet.insertRow() works now, even if not all columns are
       set (they will be set to "NULL")

     - DataBaseMetaData.getCrossReference() no longer ArrayIndexOOB

     - getObject() on ResultSet correctly does TINYINT->Byte and
       SMALLINT->Short

12-03-00 - Version 2.0.3

     - Implemented getBigDecimal() without scale component
       for JDBC2.

     - Fixed composite key problem with updatable result sets.

     - Added detection of -/+INF for doubles.

     - Faster ASCII string operations.

     - Fixed incorrect detection of MAX_ALLOWED_PACKET, so sending
       large blobs should work now.
```

```
     - Fixed off-by-one error in java.sql.Blob implementation code.

     - Added "ultraDevHack" URL parameter, set to "true" to allow
       (broken) Macromedia UltraDev to use the driver.

04-06-00 - Version 2.0.1

     - Fixed RSMD.isWritable() returning wrong value.
       Thanks to Moritz Maass.

     - Cleaned up exception handling when driver connects

     - Columns that are of type TEXT now return as Strings
       when you use getObject()

     - DatabaseMetaData.getPrimaryKeys() now works correctly wrt
       to key_seq. Thanks to Brian Slesinsky.

     - No escape processing is done on PreparedStatements anymore
       per JDBC spec.

     - Fixed many JDBC-2.0 traversal, positioning bugs, especially
       wrt to empty result sets. Thanks to Ron Smits, Nick Brook,
       Cessar Garcia and Carlos Martinez.

     - Fixed some issues with updatability support in ResultSet when
       using multiple primary keys.

02-21-00 - Version 2.0pre5

     - Fixed Bad Handshake problem.

01-10-00 - Version 2.0pre4

     - Fixes to ResultSet for insertRow() - Thanks to
       Cesar Garcia

     - Fix to Driver to recognize JDBC-2.0 by loading a JDBC-2.0
       class, instead of relying on JDK version numbers. Thanks
       to John Baker.

     - Fixed ResultSet to return correct row numbers

     - Statement.getUpdateCount() now returns rows matched,
       instead of rows actually updated, which is more SQL-92
       like.

10-29-99

     - Statement/PreparedStatement.getMoreResults() bug fixed.
       Thanks to Noel J. Bergman.

     - Added Short as a type to PreparedStatement.setObject().
       Thanks to Jeff Crowder

     - Driver now automagically configures maximum/preferred packet
       sizes by querying server.

     - Autoreconnect code uses fast ping command if server supports
       it.

     - Fixed various bugs wrt. to packet sizing when reading from
       the server and when alloc'ing to write to the server.

08-17-99 - Version 2.0pre

     - Now compiles under JDK-1.2. The driver supports both JDK-1.1
       and JDK-1.2 at the same time through a core set of classes.
       The driver will load the appropriate interface classes at
```

```
      runtime by figuring out which JVM version you are using.

    - Fixes for result sets with all nulls in the first row.
      (Pointed out by Tim Endres)

    - Fixes to column numbers in SQLExceptions in ResultSet
      (Thanks to Blas Rodriguez Somoza)

    - The database no longer needs to specified to connect.
      (Thanks to Christian Motschke)

07-04-99 - Version 1.2b

    - Better Documentation (in progress), in doc/mm.doc/book1.html

    - DBMD now allows null for a column name pattern (not in
      spec), which it changes to '%'.

    - DBMD now has correct types/lengths for getXXX().

    - ResultSet.getDate(), getTime(), and getTimestamp() fixes.
      (contributed by Alan Wilken)

    - EscapeProcessor now handles \{ \} and { or } inside quotes
      correctly. (thanks to Alik for some ideas on how to fix it)

    - Fixes to properties handling in Connection.
      (contributed by Juho Tikkala)

    - ResultSet.getObject() now returns null for NULL columns
      in the table, rather than bombing out.
      (thanks to Ben Grosman)

    - ResultSet.getObject() now returns Strings for types
      from MySQL that it doesn't know about. (Suggested by
      Chris Perdue)

    - Removed DataInput/Output streams, not needed, 1/2 number
      of method calls per IO operation.

    - Use default character encoding if one is not specified. This
      is a work-around for broken JVMs, because according to spec,
      EVERY JVM must support "ISO8859_1", but they don't.

    - Fixed Connection to use the platform character encoding
      instead of "ISO8859_1" if one isn't explicitly set. This
      fixes problems people were having loading the character-
      converter classes that didn't always exist (JVM bug).
      (thanks to Fritz Elfert for pointing out this problem)

    - Changed MysqlIO to re-use packets where possible to reduce
      memory usage.

    - Fixed escape-processor bugs pertaining to {} inside
      quotes.

04-14-99 - Version 1.2a

    - Fixed character-set support for non-Javasoft JVMs
      (thanks to many people for pointing it out)

    - Fixed ResultSet.getBoolean() to recognize 'y' & 'n'
      as well as '1' & '0' as boolean flags.
      (thanks to Tim Pizey)

    - Fixed ResultSet.getTimestamp() to give better performance.
      (thanks to Richard Swift)

    - Fixed getByte() for numeric types.
      (thanks to Ray Bellis)
```

```
     - Fixed DatabaseMetaData.getTypeInfo() for DATE type.
       (thanks to Paul Johnston)

     - Fixed EscapeProcessor for "fn" calls.
       (thanks to Piyush Shah at locomotive.org)

     - Fixed EscapeProcessor to not do extraneous work if there
       are no escape codes.
       (thanks to Ryan Gustafson)

     - Fixed Driver to parse URLs of the form "jdbc:mysql://host:port"
       (thanks to Richard Lobb)

03-24-99 - Version 1.1i

     - Fixed Timestamps for PreparedStatements

     - Fixed null pointer exceptions in RSMD and RS

     - Re-compiled with jikes for valid class files (thanks ms!)

03-08-99 - Version 1.1h

     - Fixed escape processor to deal with un-matched { and }
       (thanks to Craig Coles)

     - Fixed escape processor to create more portable (between
       DATETIME and TIMESTAMP types) representations so that
       it will work with BETWEEN clauses.
       (thanks to Craig Longman)

     - MysqlIO.quit() now closes the socket connection. Before,
       after many failed connections some OS's would run out
       of file descriptors. (thanks to Michael Brinkman)

     - Fixed NullPointerException in Driver.getPropertyInfo.
       (thanks to Dave Potts)

     - Fixes to MysqlDefs to allow all *text fields to be
       retrieved as Strings.
       (thanks to Chris at Leverage)

     - Fixed setDouble in PreparedStatement for large numbers
       to avoid sending scientific notation to the database.
       (thanks to J.S. Ferguson)

     - Fixed getScale() and getPrecision() in RSMD.
       (contrib'd by James Klicman)

     - Fixed getObject() when field was DECIMAL or NUMERIC
       (thanks to Bert Hobbs)

     - DBMD.getTables() bombed when passed a null table-name
       pattern. Fixed. (thanks to Richard Lobb)

     - Added check for "client not authorized" errors during
       connect. (thanks to Hannes Wallnoefer)

02-19-99 - Version 1.1g

     - Result set rows are now byte arrays. Blobs and Unicode
       work bidriectonally now. The useUnicode and encoding
       options are implemented now.

     - Fixes to PreparedStatement to send binary set by
       setXXXStream to be sent un-touched to the MySQL server.

     - Fixes to getDriverPropertyInfo().
```

12-31-98 - Version 1.1f

- Changed all ResultSet fields to Strings, this should allow Unicode to work, but your JVM must be able to convert between the character sets. This should also make reading data from the server be a bit quicker, because there is now no conversion from StringBuffer to String.

- Changed PreparedStatement.streamToString() to be more efficient (code from Uwe Schaefer).

- URL parsing is more robust (throws SQL exceptions on errors rather than NullPointerExceptions)

- PreparedStatement now can convert Strings to Time/Date values via setObject() (code from Robert Currey).

- IO no longer hangs in Buffer.readInt(), that bug was introduced in 1.1d when changing to all byte-arrays for result sets. (Pointed out by Samo Login)

11-03-98 - Version 1.1b

- Fixes to DatabaseMetaData to allow both IBM VA and J-Builder to work. Let me know how it goes. (thanks to Jac Kersing)

- Fix to ResultSet.getBoolean() for NULL strings (thanks to Barry Lagerweij)

- Beginning of code cleanup, and formatting. Getting ready to branch this off to a parallel JDBC-2.0 source tree.

- Added "final" modifier to critical sections in MysqlIO and Buffer to allow compiler to inline methods for speed.

9-29-98

- If object references passed to setXXX() in PreparedStatement are null, setNull() is automatically called for you. (Thanks for the suggestion goes to Erik Ostrom)

- setObject() in PreparedStatement will now attempt to write a serialized representation of the object to the database for objects of Types.OTHER and objects of unknown type.

- Util now has a static method readObject() which given a ResultSet and a column index will re-instantiate an object serialized in the above manner.

9-02-98 - Vesion 1.1

- Got rid of "ugly hack" in MysqlIO.nextRow(). Rather than catch an exception, Buffer.isLastDataPacket() was fixed.

- Connection.getCatalog() and Connection.setCatalog() should work now.

- Statement.setMaxRows() works, as well as setting by property maxRows. Statement.setMaxRows() overrides maxRows set via properties or url parameters.

- Automatic re-connection is available. Because it has to "ping" the database before each query, it is turned off by default. To use it, pass in "autoReconnect=true" in the connection URL. You may also change the number of reconnect tries, and the initial timeout value via "maxReconnects=n" (default 3) and "initialTimeout=n" (seconds, default 2) parameters. The timeout is an exponential backoff type of timeout, e.g. if you have initial timeout of 2 seconds, and maxReconnects of 3, then the driver

```
       will timeout 2 seconds, 4 seconds, then 16 seconds between each
       re-connection attempt.

8-24-98 - Version 1.0

     - Fixed handling of blob data in Buffer.java

     - Fixed bug with authentication packet being
       sized too small.

     - The JDBC Driver is now under the LPGL

8-14-98 -

     - Fixed Buffer.readLenString() to correctly
        read data for BLOBS.

     - Fixed PreparedStatement.stringToStream to
        correctly read data for BLOBS.

     - Fixed PreparedStatement.setDate() to not
       add a day.
       (above fixes thanks to Vincent Partington)

     - Added URL parameter parsing (?user=... and so forth).

8-04-98 - Version 0.9d

     - Big news! New package name. Tim Endres from ICE
       Engineering is starting a new source tree for
       GNU GPL'd Java software. He's graciously given
       me the org.gjt.mm package directory to use, so now
       the driver is in the org.gjt.mm.mysql package scheme.
       I'm "legal" now. Look for more information on Tim's
       project soon.

     - Now using dynamically sized packets to reduce
       memory usage when sending commands to the DB.

     - Small fixes to getTypeInfo() for parameters, and so forth.

     - DatabaseMetaData is now fully implemented. Let me
       know if these drivers work with the various IDEs
       out there. I've heard that they're working with
       JBuilder right now.

     - Added JavaDoc documentation to the package.

     - Package now available in .zip or .tar.gz.

7-28-98 - Version 0.9

     - Implemented getTypeInfo().
       Connection.rollback() now throws an SQLException
       per the JDBC spec.

     - Added PreparedStatement that supports all JDBC API
       methods for PreparedStatement including InputStreams.
       Please check this out and let me know if anything is
       broken.

     - Fixed a bug in ResultSet that would break some
       queries that only returned 1 row.

     - Fixed bugs in DatabaseMetaData.getTables(),
       DatabaseMetaData.getColumns() and
       DatabaseMetaData.getCatalogs().

     - Added functionality to Statement that allows
```

```
        executeUpdate() to store values for IDs that are
        automatically generated for AUTO_INCREMENT fields.
        Basically, after an executeUpdate(), look at the
        SQLWarnings for warnings like "LAST_INSERTED_ID =
        'some number', COMMAND = 'your SQL query'".

        If you are using AUTO_INCREMENT fields in your
        tables and are executing a lot of executeUpdate()s
        on one Statement, be sure to clearWarnings() every
        so often to save memory.

7-06-98 - Version 0.8

     - Split MysqlIO and Buffer to separate classes. Some
       ClassLoaders gave an IllegalAccess error for some
       fields in those two classes. Now mm.mysql works in
       applets and all classloaders.

       Thanks to Joe Ennis <jce@mail.boone.com> for pointing
       out the problem and working on a fix with me.

7-01-98 - Version 0.7

     - Fixed DatabaseMetadata problems in getColumns() and
       bug in switch statement in the Field constructor.

       Thanks to Costin Manolache <costin@tdiinc.com> for
       pointing these out.

5-21-98 - Version 0.6

     - Incorporated efficiency changes from
       Richard Swift <Richard.Swift@kanatek.ca> in
       MysqlIO.java and ResultSet.java

     - We're now 15% faster than gwe's driver.

     - Started working on DatabaseMetaData.

       The following methods are implemented:
        * getTables()
        * getTableTypes()
        * getColumns
        * getCatalogs()
```

26.4. MySQL Connector/MXJ

26.4.1. Introduction

MySQL Connector/MXJ is a Java Utility package for deploying and managing a MySQL database. Connector/MXJ may be bundled in to an existing Java application or may be deployed as a JMX MBean. Deploying and using MySQL can be as easy as adding an additional parameter to the JDBC connection url, which will result in the database being started when the first connection is made. This makes it easy for Java developers to deploy applications which require a database by reducing installation barriers for their end-users.

MySQL Connector/MXJ makes the MySQL database appear to be a java-based component. It does this by determining what platform the system is running on, selecting the appropriate binary, and launching the executable. It will also optionally deploy an initial database, with any specified parameters.

As a JMX MBean, MySQL Connector/MXJ requires a JMX v1.2 compliant MBean container, such as JBoss version 4. The MBean will uses the standard JMX management APIs to present (and allow the setting of) parameters which are appropriate for that platform.

Included are instructions for use with a JDBC driver and deploying as a JMX MBean to JBoss.

You can download sources and binaries from: http://dev.mysql.com/downloads/connector/mxj/ [http://dev.mysql.com/downloads/connector/mxj/]

This an beta release and feedback is welcome and encouraged.

Please send questions or comments to java@lists.mysql.com [mailto:java@lists.mysql.com].

26.4.2. Support Platforms:

- Linux, i386
- Windows NT, x86
- Windows 2000, x86
- Windows XP, x86
- Solaris 9, SPARC 32

26.4.3. JUnit Test Requirements

The best way to ensure that your platform is supported is to run the JUnit tests.

The first thing to do is make sure that the components will work on the platform. Since the "MysqldResource" class is really a wrapper for a native version of MySQL, not all platforms are supported. At the time of this writing, Linux on the i386 architecture has been tested and seems to work quite well, as does OS X v10.3. There has been limited testing on Windows and Solaris.

Requirements:

1. JDK-1.4 or newer (or the JRE if you aren't going to be compiling the source or JSPs).
2. MySQL Connector/J version 3.1 or newer (from http://dev.mysql.com/downloads/connector/j/ [http://dev.mysql.com/downloads/connector/j/]) installed and available via your CLASSPATH.
3. The `javax.management` classes for JMX version 1.2.1, these are present in the following application servers:
   - JBoss - 4.0rc1 or newer
   - Apache Tomcat - 5.0 or newer
   - Sun's JMX reference implementation version 1.2.1 http://java.sun.com/products/JavaManagement/ [http://java.sun.com/products/JavaManagement/]
4. Junit 3.8.1 (from http://www.junit.org/)

If building from source, All of the requirements from above, plus:

1. Ant version 1.5 or newer (download from http://ant.apache.org/)

26.4.4. Running the JUnit Tests

1. The tests attempt to launch MySQL on the port 3336. If you have a MySQL running, it may conflict, but this isn't very likely since thedefault port for MySQL is 3306. However, You may set the "c-mxj_test_port" Java property to a port of your choosing. Alternatively, you may wish to start by shutting down any instances of MySQL you have running on the target machine.

   The tests surpress output to the console by default. For verbose output, you may set the "c-mxj_test_silent" Java property to "false".

2. In order to run the JUnit test suite, the $CLASSPATH must include the following:

   - JUnit
   - JMX
   - Connector/J
   - MySQL Connector/MXJ

3. If `connector-mxj.jar` is not present in your download, unzip MySQL Connector/MXJ source archive.

   ```
   cd mysqldjmx
   ant dist
   ```

   Then add `$TEMP/cmxj/stage/connector-mxj/connector-mxj.jar` to the CLASSPATH.

4. if you have `junit`, execute the unit tests. From the command line, type:

   ```
   java junit.textui.TestRunner com.mysql.management.AllTestsSuite
   ```

   The output should look something like this:

   ```
   ........................................
   ........................................
   ..........
   Time: 259.438

   OK (101 tests)
   ```

   Note that the tests are a bit slow near the end, so please be patient.

26.4.5. Running as part of the JDBC Driver

A feature of the MySQL Connector/J JDBC driver is the ability to specify a "SocketFactory" as a parameter in the JDBC connection string. MySQL Connector/MXJ includes a custom SocketFactory. The SocketFactory will, upon the first connection, deploy and launch the MySQL database. The SocketFactory also exposes a "shutdown" method.

To try it specify the "socketFactory" parameter on the JDBC connection string with a value equal to "com.mysql.management.driverlaunched.ServerLauncherSocketFactory"

In the following example, we have a program which creates a connection, executes a query, and prints the result to the System.out. The MySQL database will be deployed and started as part of the connection process, and shutdown as part of the finally block.

```
import java.sql.Connection;
import java.sql.DriverManager;
```

```
import java.sql.ResultSet;
import java.sql.Statement;

import com.mysql.management.driverlaunched.ServerLauncherSocketFactory;

public class ConnectorMXJTestExample {
    public static void main(String[] args) throws Exception {
        String hostColonPort = "localhost:3336";

        String driver = com.mysql.jdbc.Driver.class.getName();
        String url = "jdbc:mysql://" + hostColonPort + "/" + "?"
                + "socketFactory="
                + ServerLauncherSocketFactory.class.getName();
        String userName = "root";
        String password = "";

        Class.forName(driver);
        Connection conn = null;
        try {
            conn = DriverManager.getConnection(url, userName, password);
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("SELECT VERSION()");
            rs.next();
            String version = rs.getString(1);
            rs.close();
            stmt.close();

            System.out.println("-------------------------");
            System.out.println(version);
            System.out.println("-------------------------");
        } finally {
            try {
                conn.close();
            } catch (Exception e) {
                e.printStackTrace();
            }
            ServerLauncherSocketFactory.shutdown(hostColonPort);
        }
    }
}
```

To run the above program, be sure to have connector-mxj.jar and Connector/J in the CLASSPATH. Then type:

```
java ConnectorMXJTestExample
```

Of course there are many options we may wish to set for a MySQL database. These options may be specified as part of the JDBC connection string simply by prefixing each server option with "server.". In the following example we set three driver parameters and two server parameters:

```
        String url = "jdbc:mysql://" + hostColonPort + "/"
                + "?"
                + "socketFactory="
                + ServerLauncherSocketFactory.class.getName();
                + "&"
                + "cacheServerConfiguration=true"
                + "&"
                + "useLocalSessionState=true"
                + "&"
                + "server.basedir=/opt/myapp/db"
                + "&"
                + "server.datadir=/mnt/bigdisk/myapp/data";
```

26.4.6. Running within a Java Object

Have a java application and wish to "embed" a MySQL database, make use of the com.mysql.management.MysqldResource class directly. This class may be instantiated with the default (no argument) constructor, or by passing in a java.io.File object representing the directory you wish the server to be "unzipped" into. It may also be instantiated with printstreams for "stdout" and "stderr" for logging.

Once instantiated, a java.util.Map, the object will be able to provide a java.util.Map of server options appropriate for the platform and version of MySQL which you will be using.

The MysqldResource will allow you to "start" MySQL with a java.util.Map of server options which you provide, as well as "shutdown" the database. The following example shows a simplistic way to embed MySQL in an application using plain java objects:

```
import com.mysql.management.MysqldResource;

 ...

    public void startMySQL() {
        File baseDir = new File(ourAppDir, "mysql");
        mysqldResource = new MysqldResource(baseDir);
        Map options = new HashMap();
        options.put("port", "3336");
        String threadName = "OurApp MySQL";
        mysqldResource.start(threadName, options);
    }

    public void stopMySQL() {
        if (mysqldResource != null) {
            mysqldResource.shutdown();
        }
        mysqldResource = null;
    }

    public java.sql.Connection getConnection() throws Exception {
        String db = "test";
        String url = "jdbc:mysql://localhost:3336/" + db;
        String userName = "root";
        String password = "";
        Class.forName(com.mysql.jdbc.Driver.class.getName());
        return DriverManager.getConnection(url, userName, password);
    }
```

26.4.7. The MysqldResource API

Constructors:

- public MysqldResource(File baseDir, PrintStream out, PrintStream err);

  Allows the setting of the "basedir" to deploy the MySQL files to, as well as out put streams for standard out and standard err.

- public MysqldResource(File baseDir);

  Allows the setting of the "basedir" to deploy the MySQL files to. Output for standard out and standard err are directed to System.out and System.err.

- public MysqldResource();

  The basedir is defaulted to a subdirectory of the java.io.tempdir. Output for standard out and standard err are directed to System.out and System.err;

MysqldResource API includes the following methods:

- void start(String threadName, Map mysqldArgs);

  Deploys and starts MySQL. The "threadName" string is used to name the thread which actually performs the execution of the MySQL command line. The map is the set of arguments and their values to be passed to the command line.

- void shutdown();

  Shuts down the MySQL instance managed by the MysqldResource object.

- Map getServerOptions();

  Returns a map of all the options and their current (or default, if not running) options available for the MySQL database.

- boolean isRunning();

  Returns true if the MySQL database is running.

- boolean isReadyForConnections();

  Returns true once the database reports that is ready for connections.

- void setKillDelay(int millis);

  The default "Kill Delay" is 30 seconds. This represents the amount of time to wait between the initial request to shutdown and issuing a "force kill" if the database has not shutdown by itself.

- void addCompletionListenser(Runnable listener);

  Allows for applications to be notified when the server process completes. Each "listener" will be fired off in its own thread.

- String getVersion();

  returns the version of MySQL.

- void setVersion(int MajorVersion, int minorVersion, int patchLevel);

  The standard distribution comes with only one version of MySQL packaged. However, it is possible to package multiple versions, and specify which version to use.

26.4.8. Running within a JMX Agent (custom)

If you are not using the SUN Reference implementation of the JMX libraries, you should skip this section. Or, if you are deploying to JBoss, you also may wish to skip to the next section.

We want to see the MysqldDynamicMBean in action inside of a JMX agent. In the `com.mysql.management.jmx.sunri` package is a custom JMX agent with two MBeans:

1. the MysqldDynamicMBean, and
2. a com.sun.jdmk.comm.HtmlAdaptorServer, which provides a web interface for manipulating the beans inside of a JMX agent.

When this very simple agent is started, it will allow a MySQL database to be started and stopped with a web browser.

1. Complete the testing of the platform as above.
   - current JDK, JUnit, Connector/J, MySQL Connector/MXJ
   - this section *requires* the SUN reference implementation of JMX
   - PATH, JAVA_HOME, ANT_HOME, CLASSPATH
2. If not building from source, skip to next step

   rebuild with the "sunri.present"

   ```
   ant -Dsunri.present=true dist
   re-run tests:
   java junit.textui.TestRunner com.mysql.management.AllTestsSuite
   ```

3. launch the test agent from the command line:

   ```
   java com.mysql.management.jmx.sunri.MysqldTestAgentSunHtmlAdaptor &
   ```

4. from a browser:

   ```
   http://localhost:9092/
   ```

5. under MysqldAgent,

   ```
   select "name=mysqld"
   ```

6. Observe the MBean View
7. scroll to the bottom of the screen press the startMysqld button
8. click `Back to MBean View`
9. scroll to the bottom of the screen press stopMysqld button
10. kill the java process running the Test Agent (jmx server)

26.4.9. Deployment in a standard JMX Agent environment (JBoss)

Once there is confidence that the MBean will function on the platform, deploying the MBean inside of a standard JMX Agent is the next step. Included are instructions for deploying to JBoss.

1. Ensure a current version of java development kit (v1.4.x), see above.
   - Ensure `JAVA_HOME` is set (JBoss requires `JAVA_HOME`)
   - Ensure `JAVA_HOME/bin` is in the `PATH` (You will NOT need to set your CLASSPATH, nor will you need any of the jars used in the previous tests).
2. Ensure a current version of JBoss (v4.0RC1 or better)

   ```
   http://www.jboss.org/index.html
   select "Downloads"
   ```

```
select "jboss-4.0.zip"
pick a mirror
unzip ~/dload/jboss-4.0.zip
create a JBOSS_HOME environment variable set to the unzipped directory
unix only:
cd $JBOSS_HOME/bin
chmod +x *.sh
```

3. Deploy (copy) the `connector-mxj.jar` to `$JBOSS_HOME/server/default/lib`.

4. Deploy (copy) `mysql-connector-java-3.1.4-beta-bin.jar` to `$JBOSS_HOME/server/default/lib`.

5. Create a `mxjtest.war` directory in `$JBOSS_HOME/server/default/deploy`.

6. Deploy (copy) `index.jsp` to `$JBOSS_HOME/server/default/deploy/mxjtest.war`.

7. Create a `mysqld-service.xml` file in `$JBOSS_HOME/server/default/deploy`.

```
<?xml version="1.0" encoding="UTF-8"?>
 <server>
  <mbean code="com.mysql.management.jmx.jboss.JBossMysqldDynamicMBean"
     name="mysql:type=service,name=mysqld">
  <attribute name="datadir">/tmp/xxx_data_xxx</attribute>
  <attribute name="autostart">true</attribute>
  </mbean>
 </server>
```

8. Start jboss:

   - on unix: `$JBOSS_HOME/bin/run.sh`
   - on windows: `%JBOSS_HOME%\bin\run.bat`

   Be ready: JBoss sends a lot of output to the screen.

9. When JBoss seems to have stopped sending output to the screen, open a web browser to: `http://localhost:8080/jmx-console`

10. Scroll down to the bottom of the page in the `mysql` section, select the bulleted `mysqld` link.

11. Observe the JMX MBean View page. MySQL should already be running.

12. (If "autostart=true" was set, you may skip this step.) Scroll to the bottom of the screen. You may press the Invoke button to stop (or start) MySQL observe `Operation completed successfully without a return value.` Click `Back to MBean View`

13. To confirm MySQL is running, open a web browser to `http://localhost:8080/mxjtest/` and you should see that

    ```
    SELECT 1
    ```

    returned with a result of

    ```
    1
    ```

14. Guided by the `$JBOSS_HOME/server/default/deploy/mxjtest.war/index.jsp` you will be able to use MySQL in your Web Application. There is a `test` database and a `root` user (no

password) ready to expirement with. Try creating a table, inserting some rows, and doing some selects.

15. Shut down MySQL. MySQL will be stopped automatically when JBoss is stopped, or: from the browser, scroll down to the bottom of the MBean View press the stop service Invoke button to halt the service. Observe `Operation completed successfully without a return value.` Using `ps` or `task manager` see that MySQL is no longer running

As of 1.0.6-beta version is the ability to have the MBean start the MySQL database upon start up. Also, we've taken advantage of the JBoss life-cycle extension methods so that the database will gracefully shut down when JBoss is shutdown.

26.4.10. Installation

If you've worked through the above sections, you've arleady performed these steps. But we list them here for quick reference.

Driver Launched:

1. Download and unzip Connector/MXJ, add connector-mxj.jar to the CLASSPATH

2. To the JDBC connection string add the following parameter: "socketFactory=" + Server-LauncherSocketFactory.class.getName()

JBoss:

1. Download Connector/MXJ copy the `connector-mxj.jar` file to the `$JBOSS_HOME/server/default/lib` diretory.

2. Download Connector/J copy the `connector-mxj.jar` file to the `$JBOSS_HOME/server/default/lib` diretory.

3. Create an MBean service xml file in the `$JBOSS_HOME/server/default/deploy` directory with any attributes set, for instance the `datadir` and `autostart`.

4. Set the JDBC parameters of your web application to use:
```
String driver = "com.mysql.jdbc.Driver";
String url = "jdbc:mysql:///test?propertiesTransform="+
"com.mysql.management.jmx.ConnectorMXJPropertiesTransform";
String user = "root";
String password = "";
Class.forName(driver);
Connection conn = DriverManager.getConnection(url, user, password);
```

You may wish to create a separate users and database table spaces for each application, rather than using "root and test".

We highly suggest having a routine backup procedure for backing up the database files in the `datadir`.

Chapter 27. Extending MySQL

27.1. MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. If you plan to contribute to MySQL development, want to have access to the bleeding-edge in-between versions code, or just want to keep track of development, follow the instructions in Section 2.8.3, “Installing from the Development Source Tree”. If you are interested in MySQL internals, you should also subscribe to our `internals` mailing list. This list is relatively low traffic. For details on how to subscribe, please see Section 1.7.1, “MySQL Mailing Lists”. All developers at MySQL AB are on the `internals` list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

27.1.1. MySQL Threads

The MySQL server creates the following threads:

- The TCP/IP connection thread handles all connection requests and creates a new dedicated thread to handle the authentication and SQL query processing for each connection.
- On Windows NT there is a named pipe handler thread that does the same work as the TCP/IP connection thread on named pipe connect requests.
- The signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.
- If one uses the `--flush_time=`*`val`* option, a dedicated thread is created to flush all tables at the given interval.
- Every connection has its own thread.
- Every different table on which one uses `INSERT DELAYED` gets its own thread.
- If you use `--master-host`, a slave replication thread is started to read and apply updates from the master.

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, and replication threads.

27.1.2. MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix. They cannot currently be run in a native Windows environment.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, OS/library issues, and is quite thorough in testing replication. Our eventual goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system, because this ensures that all future MySQL releases work well with your applications.

27.1.2.1. Running the MySQL Test Suite

The test system consist of a test language interpreter (`mysqltest`), a shell script to run all tests (`mysql-test-run`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` or `mysql-test/mysql-test-run` from the source root. If you have installed a binary distribution, change location to the install root (for example, `/usr/local/mysql`), and run `scripts/mysql-test-run`. All tests should succeed. If not, you should try to find out why and report the problem if this is a bug in MySQL. See Section 27.1.2.3, "How to Report Bugs in the MySQL Test Suite".

If you have a copy of `mysqld` running on the machine where you want to run the test suite you, do not have to stop it, as long as it is not using ports `9306` or `9307`. If either of those ports is taken, you should edit `mysql-test-run` and change the values of the master or slave port to one that is available.

You can run one individual test case with `mysql-test/mysql-test-run test_name`.

If one test fails, you should run `mysql-test-run` with the `--force` option to check whether any other tests fail.

27.1.2.2. Extending the MySQL Test Suite

You can use the `mysqltest` language to write your own test cases. Unfortunately, we have not yet written full documentation for it. You can, however, look at our current test cases and use them as an example. The following points should help you get started:

- The tests are located in `mysql-test/t/*.test`
- A test case consists of `;` terminated statements and is similar to the input of `mysql` command-line client. A statement by default is an SQL statement to be sent to MySQL server, unless it is recognized as internal command (for example, `sleep`).
- All queries that produce results—for example, `SELECT`, `SHOW`, or `EXPLAIN`—must be preceded with *`@/path/to/result/file`*. The file must contain the expected results. An easy way to generate the result file is to run `mysqltest -r < t/test-case-name.test` from the `mysql-test` directory, and then edit the generated result files, if needed, to adjust them to the expected output. In that case, be very careful about not adding or deleting any invisible characters. Make sure to only change the text or delete lines. If you have to insert a line, make sure that the fields are separated by a hard tab, and that there is a hard tab at the end. You may want to use `od -c` to make sure that your text editor has not messed anything up during edit. We hope that you never have to edit the output of `mysqltest -r` as you only have to do it when you find a bug.
- To be consistent with our setup, you should put your result files in the `mysql-test/r` directory and name them `test_name.result`. If the test produces more than one result, you should use `test_name.a.result`, `test_name.b.result`, and so forth.
- If a statement returns an error, you should specify it with `--error error-number` on the line before the statement. The error number can be a list of possible error numbers separated by '`,`'.
- If you are writing a replication test case, you should on the first line of the test file, put `source include/master-slave.inc;`. To switch between master and slave, use `connection master;` and `connection slave;`. If you need to do something on an alternate connection, you can do `connection master1;` for the master, and `connection slave1;` for the slave.
- If you need to do something in a loop, you can use something like this:

```
let $1=1000;
```

```
while ($1)
{
 # do your queries here
 dec $1;
}
```

- To sleep between queries, use the `sleep` command. It supports fractions of a second, so you can use `sleep 1.3;`, for example, to sleep 1.3 seconds.
- To run the slave with additional options for your test case, put them in the command-line format in `mysql-test/t/test_name-slave.opt`. For the master, put them in `mysql-test/t/test_name-master.opt`.
- If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”. This list does not accept attachments, so you should FTP all the relevant files to: ftp://ftp.mysql.com/pub/mysql/upload/

27.1.2.3. How to Report Bugs in the MySQL Test Suite

If your MySQL version doesn't pass the test suite you should do the following:

- Don't file a bug report before you have found out as much as possible of what when wrong! See the instructions at Section 1.8, “How to Report Bugs or Problems”.
- Make sure to include the output of `mysql-test-run`, as well as contents of all `.reject` files in `mysql-test/r` directory.
- If a test in the test suite fails, check whether the test fails also when run by its own:

  ```
  cd mysql-test
  mysql-test-run --local test-name
  ```

  If this fails, then you should configure MySQL with `--with-debug` and run `mysql-test-run` with the `--debug` option. If this also fails send the trace file `var/tmp/master.trace` to ftp://ftp.mysql.com/pub/mysql/upload/ so that we can examine it. Please remember to also include a full description of your system, the version of the `mysqld` binary and how you compiled it.
- Try also to run `mysql-test-run` with the `--force` option to see whether there is any other test that fails.
- If you have compiled MySQL yourself, check our manual for how to compile MySQL on your platform or, preferable, use one of the binaries we have compiled for you at http://dev.mysql.com/downloads/. All our standard binaries should pass the test suite!
- If you get an error such as `Result length mismatch` or `Result content mismatch` it means that the output of the test didn't match exactly the expected output. This could be a bug in MySQL or that your version of `mysqld` produces slightly different results under some circumstances.

  Failed test results are put in a file with the same base name as the result file with the `.reject` extension. If your test case is failing, you should do a diff on the two files. If you cannot see how they are different, examine both with `od -c` and also check their lengths.
- If a test fails totally, you should check the logs file in the `mysql-test/var/log` directory for hints of what went wrong.
- If you have compiled MySQL with debugging you can try to debug this by running `mysql-`

`test-run` with either or both of the `--gdb` and `--debug` options. See Section E.1.2, “Creating Trace Files”.

If you have not compiled MySQL for debugging you should probably do that. Just specify the `--with-debug` options to `configure`. See Section 2.8, “MySQL Installation Using a Source Distribution”.

27.2. The MySQL Plugin Interface

MySQL 5.1 and up supports a plugin API that allows the loading and unloading of server components at runtime, without restarting the server. Currently, the plugin API supports creation of full-text parser plugins. Such a plugin can be used to replace or augment the built-in full-text parser. For example, a plugin can parse text into words using rules that differ from those used by the built-in parser. This can be useful if you need to parse text with characteristics different from those expected by the built-in parser.

The plugin interface is intended as the successor to the older user-defined function (UDF) interface. The plugin interface eventually will include an API for creating UDFs, and it is intended this plugin UDF API will replace the older non-plugin UDF API. After that point, it will be possible for UDFs to be revised for use as plugin UDFs so that they can take advantage of the better security and versioning capabilities of the plugin API. Eventually, support for the older UDF API will be phased out.

The plugin interface requires the `plugin` table in the `mysql` database. This table is created as part of the MySQL installation process. If you are upgrading from an older version to MySQL 5.1, you should run the `mysql_fix_privilege_tables` command to create this table. See Section 2.10.2, “Upgrading the Grant Tables”.

27.2.1. Characteristics of the Plugin Interface

In some respects, the plugin API is similar to the older user-defined function (UDF) API that it supercedes, but the plugin API has several advantages over the older interface:

- The plugin framework is extendable to accommodate different kinds of plugins.

  Some aspects of the plugin API are common to all types of plugins, but the API also allows for type-specific interface elements so that different types of plugins can be created. A plugin with one purpose can have an interface most appropriate to its own requirements and not the requirements of some other plugin type.

  Although only the interface for full-text parser plugins is implemented currently, others can be added, such as an interface for UDF plugins.

- The plugin API includes versioning information.

  The version information included in the plugin API enables a plugin library and each plugin that it contains to be self-identifying with respect to the API version that was used to build the library. If the API changes over time, the version numbers will change, but a server can examine a given plugin library's version information to determine whether it supports the plugins in the library.

  There are two types of version numbers. The first is the version for the general plugin framework itself. Each plugin library includes this kind of version number. The second type of version applies to individual plugins. Each specific type of plugin has a version for its interface, so each plugin in a library has a type-specific version number. For example, library containing a full-text parsing plugin has a general plugin API version number, and the plugin has a version number specific to the full-text plugin interface.

- Plugin security is improved relative to the UDF interface.

The older interface for writing non-plugin UDFs allowed libraries to be loaded from any directory searched by the system's dynamic linker, and the symbols that identified the UDF library were relatively non-specific. The newer rules are more strict. A plugin library must be installed in a specific dedicated directory for which the location is controlled by the server and cannot be changed at runtime. Also, the library must contain specific symbols that identify it as a plugin library. The server will not load something as a plugin if it was not built as a plugin.

The newer plugin interface eliminates the security issues of the older UDF interface. When a UDF plugin type is implemented, that will allow non-plugin UDFs to be brought into the plugin framework and the older interface to be phased out.

The plugin implementation includes the following components:

Source files (the locations given indicate where the files are found in a MySQL source distribution):

- `include/plugin.h` exposes the public plugin API. This file should be examined by anyone who wants to write a plugin library.
- `sql/sql_plugin.h` and `sql/sql_plugin.cc` comprise the internal plugin implementation. These files need not be consulted by plugin writers. They may be of interest for those who want to know more about how the server handles plugins.

System table:

- The `plugin` table in the `mysql` database lists each installed plugin and is required for plugin use. For new MySQL installations, this table is created during the installation process. If you are upgrading from a version older than MySQL 5.1, you should run `mysql_fix_privilege_tables` to update your system tables and create the `plugin` table.

SQL statements:

- `INSTALL PLUGIN` registers a plugin in the `plugin` table and loads the plugin code.
- `UNINSTALL PLUGIN` unregisters a plugin from the `plugin` table and unloads the plugin code.
- The `WITH PARSER` clause for full-text index creation associates a full-text parser plugin with a given `FULLTEXT` index.

System variable:

- `plugin_dir` indicates the location of the directory where all plugins must be installed. The value of this variable can be specified at server startup with a `--plugin_dir=`*`path`* option.

27.2.2. Full-Text Parser Plugins

MySQL has a built-in parser that it uses by default for full-text operations (parsing text to be indexed, or parsing a query string to determine the terms to be used for a search). For full-text processing, “parsing” means extracting words from text or a query string based on rules that define which character sequences make up a word and where word boundaries lie.

When parsing for indexing purposes, the parser passes each word to the server, which adds it to a full-text index. When parsing a query string, the parser passes each word to the server, which accu-

mulates the words for use in a search.

The parsing properties of the built-in full-text parser are described in Section 12.7, “Full-Text Search Functions”. These properties include rules for determining how to extract words from text. The parser is influenced by certain system variables such as `ft_min_word_len` and `ft_max_word_len` that cause words shorter or longer to be excluded, and by the stopword list that identifies common words to be ignored.

The plugin API enables you to provide a full-text parser of your own so that you have control over the basic duties of a parser. A parser plugin can operate in either of two roles:

- The plugin can replace the built-in parser. In this role, the plugin reads the input to be parsed, splits it up into words, and passes the words to the server (either for indexing or for word accumulation).

  One reason to use a parser this way is that you need to use different rules from those of the built-in parser for determining how to split up input into words. For example, the built-in parser considers the text “case-sensitive” to consist of two words “case” and “sensitive”, whereas an application might need to treat the text as a single word.

- The plugin can act in conjunction with the built-in parser by serving as a front end for it. In this role, the plugin extracts text from the input and passes the text to the parser, which splits up the text into words using its normal parsing rules. In particular, this parsing will be affected by the `ft_`*`xxx`* system variables and the stopword list.

  One reason to use a parser this way is that you need to index content such as PDF documents, XML documents, or `.doc` files. The built-in parser is not intended for those types of input but a plugin can pull out the text from these input sources and pass it to the built-in parser.

It is also possible for a parser plugin to operate in both roles. That is, it could extract text from non-plaintext input (the front end role), and also parse the text into words (thus replacing the built-in parser).

A full-text plugin is associated with full-text indexes on a per-index basis. That is, when you install a parser plugin initially, that does not cause it to be used for any full-text operations. It simply becomes available. For example, a full-text parser plugin becomes available to be named in a `WITH PARSER` clause when creating individual `FULLTEXT` indexes. To create such an index at table-creation time, do this:

```
CREATE TABLE t
(
  doc CHAR(255),
  FULLTEXT INDEX (doc) WITH PARSER my_parser
);
```

Or you can add the index after the table has been created:

```
ALTER TABLE t ADD FULLTEXT INDEX (doc) WITH PARSER my_parser;
```

The only SQL change for associating the parser with the index is the `WITH PARSER` clause. Searches are specified as before, with no changes needed for queries.

When you associate a parser plugin with a `FULLTEXT` index, the plugin is required for using the index. If the parser plugin is dropped, any index associated with it becomes unusable. Any attempt to use it a table for which a plugin is not available results in an error, although `DROP TABLE` is still possible.

27.2.3. `INSTALL PLUGIN` Syntax

```
INSTALL PLUGIN plugin_name SONAME 'plugin_library'
```

This statement installs a plugin.

plugin_name is the name of the plugin as defined in the plugin declaration structure contained in the library file. Plugin name case sensitivity is determined by the host system filename semantics.

plugin_library is the name of the shared library that contains the plugin code. The name includes the filename extension (for example, libmyplugin.so or libmyplugin.dylib).

The shared library must be located in the plugin directory (that is, the directory named by the plugin_dir system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, plugin_dir is the directory named by the pkglibdir configuration variable, but it can be changed by setting the value of plugin_dir at server startup. For example, set its value in a my.cnf file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative pathname, it is taken to be relative to the MySQL base directory (the value of the basedir system variable).

INSTALL PLUGIN adds a line to the mysql.plugin table that describes the plugin. This table contains the plugin name and library filename.

INSTALL PLUGIN also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use INSTALL PLUGIN, you must have the INSERT privilege for the mysql.plugin table.

At server startup, the server loads and initializes any plugin that is listed in the mysql.plugin table. This means that a plugin is installed with INSTALL PLUGIN only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the --skip-grant-tables option.

When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a change to perform any final cleanup.

To remove a plugin entirely, use the UNINSTALL PLUGIN statement:

If you recompile a plugin library and need to reinstall it, you can use either of the following procedures:

- Use UNINSTALL PLUGIN to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use INSTALL PLUGIN to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many INSTALL PLUGIN and UNINSTALL PLUGIN statements.
- Alternatively, stop the server, install the new plugin library file in the plugin directory, and then restart the server.

27.2.4. UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed plugin. You cannot uninstall a plugin if any table that uses it is open.

plugin_name must be the name of some plugin that is listed in the mysql.plugin table. The server executes the plugin's deinitialization function and removes the row for the plugin from the mysql.plugin table, so that subsequent server restarts will not load and initialize the plugin. UNINSTALL PLUGIN does not remove the plugin's shared library file.

To use UNINSTALL PLUGIN, you must have the DELETE privilege for the mysql.plugin table.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a FULLTEXT index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with mysqldump and remove the WITH PARSER clause from the dumped CREATE TABLE statement so that you can reload the table later. If you do not care about the table, DROP TABLE can be used even if any plugins associated with the table are missing.

27.2.5. Writing Plugins

This section describes the general and type-specific parts of the plugin API. It also provides a step-by-step guide to creating a plugin library.

You can write plugins in C or C++. Plugins are loaded and unloaded dynamically, so your operating system must support dynamic loading and you must have compiled mysqld dynamically (not statically).

A plugin contains code that becomes part of the running server, so when you write a plugin, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the libstdc++ library. Note that these constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to plugins that were originally written for older servers. For information about these constraints, see Section 2.8.2, “Typical configure Options”, and Section 2.8.4, “Dealing with Problems Compiling MySQL”.

27.2.5.1. General Plugin Structures and Functions

Every plugin must have a general plugin declaration. The declaration corresponds to the st_mysql_plugin structure in the plugin.h file:

```
struct st_mysql_plugin
{
  int type;            /* the plugin type (a MYSQL_XXX_PLUGIN value)   */
  void *info;          /* pointer to type-specific plugin descriptor   */
  const char *name;    /* plugin name                                  */
  const char *author;  /* plugin author (for SHOW PLUGINS)             */
  const char *descr;   /* general descriptive text (for SHOW PLUGINS ) */
  int (*init)(void);   /* the function to invoke when plugin is loaded */
  int (*deinit)(void); /* the function to invoke when plugin is unloaded */
};
```

The st_mysql_plugin structure is common to every type of plugin. Its members should be filled in as follows:

- type

  The plugin type. This must be one of the plugin-type values from plugin.h. For a full-text parser plugin, the type value is MYSQL_FTPARSER_PLUGIN.

- info

A pointer to the descriptor for the plugin. Unlike the general plugin declaration structure, this descriptor's structure depends on the particular type of plugin. Each descriptor has a version number that indicates the API version for that type of plugin, plus any other members needed. The descriptor for full-text plugins is described in Section 27.2.5.2, “Type-Specific Plugin Structures and Functions”.

- `name`

  The plugin name. This is the name that will be listed in the `plugin` table and by which you refer to the plugin in SQL statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- `author`

  The plugin author. This can be whatever you like.

- `desc`

  A general description of the plugin. This can be whatever you like.

- `init`

  A once-only initialization function. This is executed when the plugin is loaded, which happens for `INSTALL PLUGIN` or, for plugins listed in the `plugin` table, at server startup. The function takes no arguments. It returns zero for success and non-zero for failure.

- `deinit`

  A once-only deinitialization function. This is executed when the plugin is unloaded, which happens for `UNINSTALL PLUGIN` or, for plugins listed in the `plugin` table, at server shutdown. The function takes no arguments. It returns zero for success and non-zero for failure.

The `init` and `deinit` functions in the general plugin declaration are invoked only when loading and unloading the plugin. They have nothing to do with use of the plugin such as happens when an SQL statement causes the plugin to be invoked.

If an `init` or `deinit` function is unneeded for a plugin, it can be specified as 0 in the `st_mysql_plugin` structure.

27.2.5.2. Type-Specific Plugin Structures and Functions

In the `st_mysql_plugin` structure that defines a plugin's general declaration, the `info` member points to a type-specific plugin descriptor. For a full-text parser plugin, the descriptor corresponds to the `st_mysql_ftparser` structure in the `plugin.h` file:

```
struct st_mysql_ftparser
{
  int interface_version;
  int (*parse)(MYSQL_FTPARSER_PARAM *param);
  int (*init)(MYSQL_FTPARSER_PARAM *param);
  int (*deinit)(MYSQL_FTPARSER_PARAM *param);
};
```

As shown by the structure definition, the descriptor has a version number (`MYSQL_FTPARSER_INTERFACE_VERSION` for full-text parser plugins) and contains pointers to three functions. The `init` and `deinit` members should point to a function or be set to 0 if the function is not needed. The `parse` member must point to the function that performs the parsing.

A full-text parser plugin is used in two different contexts, indexing and searching. In both contexts, the server calls the initialization and deinitialization functions at the beginning and end of processing each SQL statement that causes the plugin to be invoked. However, during statement processing, the server calls the main parsing function in context-specific fashion:

- For indexing, the server calls the parser for each column value to be indexed.
- For searching, the server calls the parser to parse the search string. The parser might also be called for rows processed by the statement. In natural language mode, there is no need for the server to call the parser. For boolean mode phrase searches or natural language searches with query expansion, the parser is used to parse column values for information that is not in the index. Also, if a boolean mode search is done for a column that has no `FULLTEXT` index, the built-in parser will be called. (Plugins are associated with specific indexes. If there is no index, no plugin is used.)

Note that the plugin declaration in the plugin library descriptor has initialization and deinitialization functions, and so does the plugin descriptor to which it points. These pairs of functions have different purposes and are invoked for different reasons:

- For the plugin declaration in the plugin library descriptor, the initialization and deinitialization functions are invoked when the plugin is loaded and unloaded.
- For the plugin descriptor, the initialization and deinitialization functions are invoked per SQL statement for which the plugin is used.

Each interface function named in the plugin descriptor should return zero for success or non-zero for failure, and each of them receives an argument that points to a `MYSQL_FTPARSER_PARAM` structure containing the parsing context. The structure has this definition:

```
typedef struct st_mysql_ftparser_param
{
  int (*mysql_parse)(void *param, byte *doc, uint doc_len);
  int (*mysql_add_word)(void *param, byte *word, uint word_len,
                        MYSQL_FTPARSER_BOOLEAN_INFO *boolean_info);
  void *ftparser_state;
  void *mysql_ftparam;
  CHARSET_INFO *cs;
  byte *doc;
  uint length;
  int mode;
} MYSQL_FTPARSER_PARAM;
```

The structure members are used as follows:

- `mysql_parse`

  A pointer to a callback function that invokes the server's built-in parser. Use this callback when the plugin acts as a front end to the built-in parser. That is, when the plugin parsing function is called, it should process the input to extract the text and pass the text to the `mysql_parse` callback.

  The first parameter for this callback function should be the `mysql_ftparam` member of the parsing context structure. That is, if `param` points to the structure, invoke the callback like this:

  ```
  param->mysql_parse(param->mysql_ftparam, ...);
  ```

  A front end plugin can extract text and pass it all at once to the built-in parser, or it can extract and pass text to the built-in parser a piece at a time. However, in this case, the built-in parser treats the pieces of text as though there are implicit word breaks between them.

- `mysql_add_word`

  A pointer to a callback function that adds a word to a full-text index or to the list of search terms. Use this callback when the parser plugin replaces the built-in parser. That is, when the

plugin parsing function is called, it should parse the input into words and invoke the `mysql_add_word` callback for each word.

The first parameter for this callback function should be the `mysql_ftparam` member of the parsing context structure. That is, if `param` points to the structure, invoke the callback like this:

```
param->mysql_add_word(param->mysql_ftparam, ...);
```

- `ftparser_state`

  This is a generic pointer. The plugin can set it to point to information to be used internally for its own purposes.

- `mysql_ftparam`

  This is set by the server. It is passed as the first argument to the `mysql_parse` or `mysql_add_word` callback.

- `cs`

  A pointer to information about the character set of the text, or 0 if no information is available.

- `doc`

  A pointer to the text to be parsed.

- `length`

  The length of the text to be parsed, in bytes.

- `mode`

  The parsing mode. This value will be one of the folowing constants:

  - `MYSQL_FTPARSER_SIMPLE_MODE`

    Parse in fast and simple mode, which is used for indexing and for natural language queries. The parser should pass to the server only those words that should be indexed. If the parser uses length limits or a stopword list to determine which words to ignore, it should not pass such words to the server.

  - `MYSQL_FTPARSER_WITH_STOPWORDS`

    Parse in stopword mode. This is used in boolean searches for phrase matching. The parser should pass all words to the server, even stopwords or words that are outside any normal length limits.

  - `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`

    Parse in boolean mode. This is used for parsing boolean query strings. The parser should recognize not only words but also boolean-mode operators and pass them to the server as tokens via the `mysql_add_word` callback. To tell the server what kind of token is being passed, the plugin needs to fill in a `MYSQL_FTPARSER_BOOLEAN_INFO` structure and pass a pointer to it.

If the parser is called in boolean mode, the `param->mode` value will be `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`. The `MYSQL_FTPARSER_BOOLEAN_INFO` structure that the parser uses for passing token information to the server looks like this:

```
typedef struct st_mysql_ftparser_boolean_info
{
  enum enum_ft_token_type type;
```

```
  int yesno;
  int weight_adjust;
  bool wasign;
  bool trunc;
  /* These are parser state and must be removed. */
  byte prev;
  byte *quot;
} MYSQL_FTPARSER_BOOLEAN_INFO;
```

The parser should fill in the structure members as follows:

- `type`

  The token type. This should be one of values shown in the following table:

Type	Meaning
`FT_TOKEN_EOF`	End of data
`FT_TOKEN_WORD`	A regular word
`FT_TOKEN_LEFT_PAREN`	The beginning of a group or subexpression
`FT_TOKEN_RIGHT_PAREN`	The end of a group or subexpression
`FT_TOKEN_STOPWORD`	A stopword

- `yesno`

  Whether the word must be present for a match to occur. 0 means that the word is optional but increases the match relevance if it is present. Values larger than 0 mean that the word must be present. Values smaller than 0 mean that the word must not be present.

- `weight_adjust`

  A weighting factor that determines how much a match for the word counts. It can be used to increase or decrease the word's importance in relevance calculations. A value of zero indicates no weight adjustment. Values greater than or less than zero mean higher or lower weight, respectively. The examples at Section 12.7.1, “Boolean Full-Text Searches”, that use the < and > operators illustrate how weighting works.

- `wasign`

  The sign of the weighting factor. A negative value acts like the ~ boolean-search operator, which causes the word's contribution to the relevance to be negative.

- `trunc`

  Whether matching should be done as if the boolean-mode * truncation operator had been given.

Plugins should not use the `prev` and `quot` members of the `MYSQL_FTPARSER_BOOLEAN_INFO` structure.

27.2.5.3. Creating a Plugin Library

This section provides a step-by-step procedure for creating a plugin library. It shows how to develop a library that contains a full-text parsing plugin named `simple_parser`. This plugin performs parsing based on simpler rules than those used by the MySQL built-in full-text parser: Words are non-empty runs of whitespace characters.

Each plugin library has the following contents:

- A plugin library descriptor that indicates the version number of the general plugin API that the library uses and that contains a general declaration for each plugin in the library.
- Each plugin general declaration contains information that is common to all types of plugin: A value that indicates the plugin type; the plugin name, author, and description; and pointers to the initialization and deinitialization functions that the server invokes when it loads and unloads the plugin.
- The plugin general declaration also contains a pointer to a type-specific plugin descriptor. The structure of these descriptors can vary from one plugin type to another, because each type of plugin can have its own API. A plugin descriptor contains a type-specific API version number and pointers to the functions that are needed to implement that plugin type. For example, a full-text parser plugin has initialization and deinitialization functions, and a main parsing function. The server invokes these functions when it uses the plugin to parse text.
- The plugin library contains the interface functions that are referenced by the library descriptor and by the plugin descriptors.

To create a plugin library, follow these steps:

1. Include the header files that the plugin library needs. The `plugin.h` file is required, and the library might require other files as well. For example:

   ```
   #include <my_global.h>
   #include <m_string.h>
   #include <m_ctype.h>
   #include <plugin.h>
   ```

2. Set up the plugin library file descriptor.

   Every plugin library must include a library descriptor that must define two symbols:

   - `_mysql_plugin_interface_version_` specifies the version number of the general plugin framework. This is given by the `MYSQL_PLUGIN_INTERFACE_VERSION` symbol, which is defined in the `plugin.h` file.
   - `_mysql_plugin_declarations_` defines an array of plugin declarations, terminated by a declaration with all members set to 0. Each declaration is an instance of the `st_mysql_plugin` structure (also defined in `plugin.h`). There must be one of these for each plugin in the library.

   If the server does not find these two symbols in a library, it does not accept it as a legal plugin library and rejects it with an error. This prevents use of a library for plugin purposes unless it was built specifically as a plugin library.

   The standard (and most convenient) way to define the two required symbols is by using the `mysql_declare_plugin` and `mysql_declare_plugin_end` macros from the `plugin.h` file:

   ```
   mysql_declare_plugin
    ... one or more plugin declarations here ...
   mysql_declare_plugin_end;
   ```

   For example, the library descriptor for a library that contains a single plugin named `simple_parser` looks like this:

   ```
   mysql_declare_plugin
   {
     MYSQL_FTPARSER_PLUGIN,      /* type                            */
     &simple_parser_descriptor,  /* descriptor                      */
     "simple_parser",            /* name                            */
   ```

```
  "MySQL AB",                  /* author                    */
  "Simple Full-Text Parser",  /* description               */
  simple_parser_plugin_init,  /* initialization function   */
  simple_parser_plugin_deinit /* deinitialization function */
}
mysql_declare_plugin_end;
```

For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

The `mysql_declare_plugin` and `mysql_declare_plugin_end` macros are defined in `plugin.h` like this:

```
#define mysql_declare_plugin                                            \
int _mysql_plugin_interface_version_= MYSQL_PLUGIN_INTERFACE_VERSION; \
struct st_mysql_plugin _mysql_plugin_declarations_[]= {
#define mysql_declare_plugin_end ,{0,0,0,0,0,0,0}}
```

When the macros are used as just shown, they expand to the following code, which defines both of the required symbols (`_mysql_plugin_interface_version_` and `_mysql_plugin_declarations_`):

```
int _mysql_plugin_interface_version_= MYSQL_PLUGIN_INTERFACE_VERSION;
struct st_mysql_plugin _mysql_plugin_declarations_[]= {
{
  MYSQL_FTPARSER_PLUGIN,      /* type                      */
  &simple_parser_descriptor,  /* descriptor                */
  "simple_parser",            /* name                      */
  "MySQL AB",                 /* author                    */
  "Simple Full-Text Parser",  /* description               */
  simple_parser_plugin_init,  /* initialization function   */
  simple_parser_plugin_deinit /* deinitialization function */
}
  ,{0,0,0,0,0,0,0}
};
```

The preceding example declares a single plugin in the library descriptor, but it is possible to declare multiple plugins. List the declarations one after the other between `mysql_declare_plugin` and `mysql_declare_plugin_end`, separated by commas.

3. Set up the plugin descriptor.

   Each plugin declaration in the library descriptor points to a type-specific descriptor for the corresponding plugin. In the `simple_parser` declaration, that descriptor is indicated by `&simple_parser_descriptor`. The descriptor specifies the version number for the full-text plugin interface (as given by `MYSQL_FTPARSER_INTERFACE_VERSION`), and the plugin's parsing, initialization, and deinitialization functions:

   ```
   static struct st_mysql_ftparser simple_parser_descriptor=
   {
     MYSQL_FTPARSER_INTERFACE_VERSION, /* interface version      */
     simple_parser_parse,              /* parsing function       */
     simple_parser_init,               /* parser init function   */
     simple_parser_deinit              /* parser deinit function */
   };
   ```

4. Set up the plugin interface functions.

   The general plugin declaration in the library descriptor names the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. For `simple_parser`, these functions do nothing but return zero to indicate that they succeeded:

```
static int simple_parser_plugin_init(void)
{
  return(0);
}

static int simple_parser_plugin_deinit(void)
{
  return(0);
}
```

Because those functions do not actually do anything, you could omit them and specify 0 for each of them in the plugin declaration.

The type-specific plugin descriptor for `simple_parser` names the initialization, deinitialization, and parsing functions that the server invokes when the plugin is used. For `simple_parser`, the initialization and deinitialization functions do nothing:

```
static int simple_parser_init(MYSQL_FTPARSER_PARAM *param)
{
  return(0);
}

static int simple_parser_deinit(MYSQL_FTPARSER_PARAM *param)
{
  return(0);
}
```

Here too, because those functions do nothing, you could omit them and specify 0 for each of them in the plugin descriptor.

The main parsing function, `simple_parser_parse()`, acts as a replacement for the built-in full-text parser, so it needs to split text into words and pass each word to the server. The parsing function's first argument is a pointer to a structure that contains the parsing context. This structure has a `doc` member that points to the text to be parsed, and a `length` member that indicates how long the text is. The simple parsing done by the plugin considers non-empty runs of whitespace characters to be words, so it identifies words like this:

```
static int simple_parser_parse(MYSQL_FTPARSER_PARAM *param)
{
  char *end, *start, *docend= param->doc + param->length;

  for (end= start= param->doc;; end++)
  {
    if (end == docend)
    {
      if (end > start)
        add_word(param, start, end - start);
      break;
    }
    else if (isspace(*end))
    {
      if (end > start)
        add_word(param, start, end - start);
      start= end + 1;
    }
  }
  return(0);
}
```

As the parser finds each word, it invokes a function `add_word()` to pass the word to the server. `add_word()` is a helper function only; it is not part of the plugin interface. The parser passes the parsing context pointer to `add_word()`, as well as a pointer to the word and a length value:

```
static void add_word(MYSQL_FTPARSER_PARAM *param, char *word, size_t len)
{
  MYSQL_FTPARSER_BOOLEAN_INFO bool_info=
    { FT_TOKEN_WORD, 0, 0, 0, 0, ' ', 0 };

  if (param->mode == MYSQL_FTPARSER_FULL_BOOLEAN_INFO)
    param->mysql_add_word(param->mysql_ftparam, word, len, &bool_info);
  else
    param->mysql_add_word(param->mysql_ftparam, word, len, 0);
}
```

For boolean-mode parsing, `add_word()` fills in the members of the `bool_info` structure as described in Section 27.2.5.2, “Type-Specific Plugin Structures and Functions”.

5. Compile the plugin library as a shared library and install it in the plugin directory.

   The procedure for compiling shared objects varies from system to system. If you build your library using the GNU autotools, `libtool` should be able to generate the correct compilation commands for your system. If the library is named `mypluglib`, you should end up with a shared object file that has a name something like `libmypluglib.so`. (The filename might have a different extension on your system.)

   The location of the plugin directory where you should install the library is given by the `plugin_dir` system variable. For example:

```
mysql> SHOW VARIABLES LIKE 'plugin_dir';
+---------------+----------------------------+
| Variable_name | Value                      |
+---------------+----------------------------+
| plugin_dir    | /usr/local/mysql/lib/mysql |
+---------------+----------------------------+
```

   When you install the plugin library, make sure that its permissions allow it to be executed by the server.

6. Register the plugin with the server.

   The `INSTALL PLUGIN` statement causes the server to list the plugin in the `plugin` table and to load the plugin code from the library file. Use that statement to register `simple_parser` with the server, and then verify that the plugin is listed in the `plugin` table:

```
mysql> INSTALL PLUGIN simple_parser SONAME 'libmypluglib.so';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM mysql.plugin;
+---------------+-----------------+
| name          | dl              |
+---------------+-----------------+
| simple_parser | libmypluglib.so |
+---------------+-----------------+
1 row in set (0.00 sec)
```

7. Try the plugin.

   Create a table that contains a string column and associate the parser plugin with a `FULLTEXT` index on the column:

```
mysql> CREATE TABLE t (c VARCHAR(255),
    ->   FULLTEXT (c) WITH PARSER simple_parser);
Query OK, 0 rows affected (0.01 sec)
```

Insert some text into the table and try some searches. These should verify that the parser plugin treats all non-whitespace characters as word characters:

```
mysql> INSERT INTO t VALUES
    ->   ('latin1_general_cs is a case-sensitive collation'),
    ->   ('I\'d like a case of oranges'),
    ->   ('this is sensitive information'),
    ->   ('another row'),
    ->   ('yet another row');
Query OK, 5 rows affected (0.02 sec)
Records: 5  Duplicates: 0  Warnings: 0

mysql> SELECT c FROM t;
+-----------------------------------------------+
| c                                             |
+-----------------------------------------------+
| latin1_general_cs is a case-sensitive collation |
| I'd like a case of oranges                    |
| this is sensitive information                 |
| another row                                   |
| yet another row                               |
+-----------------------------------------------+
5 rows in set (0.00 sec)

mysql> SELECT MATCH(c) AGAINST('case') FROM t;
+--------------------------+
| MATCH(c) AGAINST('case') |
+--------------------------+
|                        0 |
|          1.2968142032623 |
|                        0 |
|                        0 |
|                        0 |
+--------------------------+
5 rows in set (0.00 sec)

mysql> SELECT MATCH(c) AGAINST('sensitive') FROM t;
+-------------------------------+
| MATCH(c) AGAINST('sensitive') |
+-------------------------------+
|                             0 |
|                             0 |
|               1.3253291845322 |
|                             0 |
|                             0 |
+-------------------------------+
5 rows in set (0.01 sec)

mysql> SELECT MATCH(c) AGAINST('case-sensitive') FROM t;
+-----------------------------------+
| MATCH(c) AGAINST('case-sensitive') |
+-----------------------------------+
|                    1.3109166622162 |
|                                  0 |
|                                  0 |
|                                  0 |
|                                  0 |
+-----------------------------------+
5 rows in set (0.01 sec)

mysql> SELECT MATCH(c) AGAINST('I\'d') FROM t;
+--------------------------+
| MATCH(c) AGAINST('I\'d') |
+--------------------------+
|                        0 |
|          1.2968142032623 |
|                        0 |
|                        0 |
```

```
|                          0 |
+----------------------------+
5 rows in set (0.01 sec)
```

Note how neither “case” nor “insensitive” match “case-insensitive” the way that they would for the built-in parser.

27.3. Adding New Functions to MySQL

There are two ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See Section 27.3.2, “`CREATE FUNCTION` Syntax”.
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.

Each method has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don't need to do that.
- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is described in Chapter 20, *Stored Procedures and Functions*.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native mySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.cc` file that is provided in MySQL source distributions.

27.3.1. Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number and types of the arguments passed to them.

- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns `NULL` or that an error occurred.

27.3.2. `CREATE FUNCTION` Syntax

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

`function_name` is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

`shared_library_name` is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. (**Note:** This a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.)

To create a function, you must have the `INSERT` and privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_fix_privilege_tables` script to create it. See Section 2.10.2, “Upgrading the Grant Tables”.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see Section 27.3.4, “Adding a New User-Defined Function”. For the UDF mechanism to work, functions must be written in C or C++, your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_fix_privilege_tables` script to create it.

27.3.3. `DROP FUNCTION` Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *`function_name`*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

27.3.4. Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. The MySQL source distribution includes a file `sql/udf_example.cc` that defines 5 new functions. Consult this file to see how UDF calling conven-

tions work.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. Note that these constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see Section 2.8.2, “Typical `configure` Options”, and Section 2.8.4, “Dealing with Problems Compiling MySQL”.

To be able to use UDFs, you need to link `mysqld` dynamically. Don't configure MySQL using `--with-mysqld-ldflags=-all-static`. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.cc` that uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`). If you plan to use UDFs, the rule of thumb is to configure MySQL with `--with-mysqld-ldflags=-rdynamic` unless you have a very good reason not to.

If you must use a precompiled distribution of MySQL, use MySQL-Max, which contains a dynamically linked server that supports dynamic loading.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

The C/C++ functions that you write to implement the interface for `XXX()` are:

- `xxx()` (required)

  The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here:

SQL Type	**C/C++ Type**
`STRING`	`char *`
`INTEGER`	`long long`
`REAL`	`double`

  It is also possible to declare a `DECIMAL` function, but currently the value is returned as a string, so you should write the UDF as though it were a `STRING` function.

- `xxx_init()` (optional)

  The initialization function for `xxx()`. It can be used for the following purposes:

  - To check the number of arguments to `XXX()`.
  - To check that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the types you want when the main function is called.
  - To allocate any memory required by the main function.
  - To specify the maximum length of the result.
  - To specify (for `REAL` functions) the maximum number of decimal places in the result.
  - To specify whether the result can be `NULL`.

- `xxx_deinit()` (optional)

  The deinitialization function for `xxx()`. It should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `XXX()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:

- `xxx_clear()` (required in 5.1)

  Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- `xxx_add()` (required)

  Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each new row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat 3-5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not allowed to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

27.3.4.1. UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. Section 27.3.4, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `XXX()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For `STRING` functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
          char *result, unsigned long *length,
          char *is_null, char *error);
```

For `INTEGER` functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

For REAL functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);

void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

  `xxx_init()` should set `maybe_null` to `1` if `xxx()` can return `NULL`. The default value is `1` if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

  The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. (For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimal digits.

- `unsigned int max_length`

  The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

  If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- `char *ptr`

  A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

  ```
  initid->ptr = allocated_memory;
  ```

  In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

  `xxx_init()` should set `const_item` to `1` if `xxx()` always returns the same value and to `0` otherwise.

27.3.4.2. UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. Section 27.3.4, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

- `xxx_reset()`

  This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

  ```
  char *xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
                  char *is_null, char *error);
  ```

  `xxx_reset()` is not needed or used in MySQL 5.1, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

  This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

  ```
  char *xxx_clear(UDF_INIT *initid, char *is_null, char *error);
  ```

  `is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

  If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

  `xxx_clear()` is required by MySQL 5.1.

- `xxx_add()`

  This function is called for all rows that belong to the same group, except for the first row. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

  ```
  char *xxx_add(UDF_INIT *initid, UDF_ARGS *args,
                char *is_null, char *error);
  ```

The `xxx()` function for an aggregate UDF should be declared the same way as for a non-aggregate UDF. See Section 27.3.4.1, “UDF Calling Sequences for Simple Functions”.

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a non-aggregate UDF. See Section 27.3.4.4, “UDF Return Values and Error Handling”.

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for non-aggregate UDFs. See Section 27.3.4.3, “UDF Argument Processing”.

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error`! `error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

27.3.4.3. UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

  The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

  ```
  if (args->arg_count != 2)
  {
      strcpy(message,"XXX() requires two arguments");
      return 1;
  }
  ```

- `enum Item_result *arg_type`

  A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, and `REAL_RESULT`.

  To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

  ```
  if (args->arg_type[0] != STRING_RESULT ||
      args->arg_type[1] != INT_RESULT)
  {
      strcpy(message,"XXX() requires a string and an integer");
      return 1;
  }
  ```

  As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

  ```
  args->arg_type[0] = STRING_RESULT;
  args->arg_type[1] = INT_RESULT;
  ```

- `char **args`

  `args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See below for instructions on how to access the value properly.) For a non-constant argument, `args->args[i]` is `0`. A constant argument is an expression that uses only constants, such as `3` or `4*7-2` or `SIN(3.14)`. A non-constant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with non-constant arguments.

  For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

  Functions can refer to an argument `i` as follows:

  - An argument of type `STRING_RESULT` is given as a string pointer plus a length, to allow handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. You should not assume

that strings are null-terminated.

- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

  ```
  long long int_val;
  int_val = *((long long*) args->args[i]);
  ```

- For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

  ```
  double    real_val;
  real_val = *((double*) args->args[i]);
  ```

- `unsigned long *lengths`

  For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

27.3.4.4. UDF Return Values and Error Handling

The initialization function should return `0` if no error occurred and `1` otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*result` and `*length` to the contents and length of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

The `result` buffer that is passed to the `xxx()` function is 255 bytes long. If your result fits in this, you don't have to worry about memory allocation for results.

If your string function needs to return a string longer than 255 bytes, you must allocate the space for it with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See Section 27.3.4.1, “UDF Calling Sequences for Simple Functions”.

To indicate a return value of `NULL` in the main function, set `*is_null` to `1`:

```
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to `1`:

```
*error = 1;
```

If `xxx()` sets `*error` to `1` for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `XXX()` was invoked. (`xxx()` is not even called for subsequent rows.)

27.3.4.5. Compiling and Installing User-Defined Functions

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.cc` that is included in the MySQL source distribution.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.cc` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it's more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP number for a hostname.
- `reverse_lookup()` returns the hostname for an IP number. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.cc
```

If you are using `gcc`, you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example.so
```

You can easily determine the correct compiler options for your system by running this command in the `sql` directory of your MySQL source tree:

```
shell> make udf_example.o
```

You should run a compile command similar to the one that `make` displays, except that you should remove the `-c` option near the end of the line and add `-o udf_example.so` to the end of the line. (On some systems, you may need to leave the `-c` on the command.)

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.cc` produces a file named something like `udf_example.so` (the exact name may vary from platform to platform). Copy this file to the server's plugin directory. This directory is given by the value of the `plugin_dir` system variable. (**Note:** This a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.)

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. You need to obtain the BitKeeper source repository for MySQL 5.1. See Section 2.8.3, “Installing from the Development Source Tree”.

2. In the source repository, look in the `VC++Files/examples/udf_example` directory. There are files named `udf_example.def`, `udf_example.dsp`, and `udf_example.dsw` there.

3. In the source repository, look in the `sql` directory. Copy the `udf_example.cc` from this directory to the `VC++Files/examples/udf_example` directory and rename the file to `udf_example.cpp`.

4. Open the `udf_example.dsw` file with Visual Studio VC++ and use it to compile the UDFs as a normal project.

After the shared object file has been installed, notify `mysqld` about the new functions with these statements:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
    ->        RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
    ->        RETURNS REAL SONAME 'udf_example.so';
```

Functions can be deleted using `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` and `DELETE` privileges for the `mysql` database to create and drop functions.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

27.3.4.6. User-Defined Function Security Precautions

MySQL takes the following measures to prevent misuse of user-defined functions.

You must have the `INSERT` privilege to be able to use `CREATE FUNCTION` and the `DELETE` privilege to be able to use `DROP FUNCTION`. This is necessary because these statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`,

, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. `mysqld` also supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

UDF object files cannot be placed in arbitrary directories. They must be located in the server's plugin directory. This directory is given by the value of the `plugin_dir` system variable. (**Note:** This a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.)

27.3.5. Adding a New Native Function

The procedure for adding a new native function is described here. Note that you cannot add native functions to a binary distribution because the procedure involves modifying MySQL source code. You must compile MySQL yourself from a source distribution. Also note that if you migrate to another version of MySQL (for example, when a new version is released), you need to repeat the procedure with the new version.

To add a new native MySQL function, follow these steps:

1. Add one line to `lex.h` that defines the function name in the `sql_functions[]` array.

2. If the function prototype is simple (just takes zero, one, two or three arguments), you should in `lex.h` specify `SYM(FUNC_ARG`*N*`)` (where *N* is the number of arguments) as the second argument in the `sql_functions[]` array and add a function that creates a function object in `item_create.cc`. Take a look at `"ABS"` and `create_funcs_abs()` for an example of this.

   If the function prototype is complicated (for example, if it takes a variable number of arguments), you should add two lines to `sql_yacc.yy`. One indicates the preprocessor symbol that `yacc` should define (this should be added at the beginning of the file). Then define the function parameters and add an “item” with these parameters to the `simple_expr` parsing rule. For an example, check all occurrences of `ATAN` in `sql_yacc.yy` to see how this is done.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.

4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

   ```
   double   Item_func_newname::val()
   longlong Item_func_newname::val_int()
   String  *Item_func_newname::Str(String *str)
   ```

   If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. You should probably also define the following object function:

   ```
   void Item_func_newname::fix_length_and_dec()
   ```

   This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the argu-

ments' `maybe_null` variable. You can take a look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, don't use any global or static variables in the functions without protecting them with mutexes)

If you want to return `NULL`, from `::val()`, `::val_int()` or `::str()` you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are some additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

27.4. Adding New Procedures to MySQL

In MySQL, you can define a procedure in C++ that can access and modify the data in a query before it is sent to the client. The modification can be done on a row-by-row or `GROUP BY` level.

We have created an example procedure to show you what can be done.

Additionally, we recommend that you take a look at `mylua`. With this you can use the LUA language to load a procedure at runtime into `mysqld`.

27.4.1. Procedure Analyse

`analyse([`*`max_elements`*`,[`*`max_memory`*`]])`

This procedure is defined in the `sql/sql_analyse.cc`. This examines the result from your query and returns an analysis of the results:

- *`max_elements`* (default 256) is the maximum number of distinct values `analyse` does notice per column. This is used by `analyse` to check whether the optimal data type should be of type `ENUM`.
- *`max_memory`* (default 8192) is the maximum amount of memory that `analyse` should allocate per column while trying to find all distinct values.

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

27.4.2. Writing a Procedure

For the moment, the only documentation for this is the source.

You can find all information about procedures by examining the following files:

- `sql/sql_analyse.cc`
- `sql/procedure.h`

- `sql/procedure.cc`
- `sql/sql_select.cc`

Appendix A. Problems and Common Errors

This appendix lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

A.1. How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problems (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard doesn't work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light doesn't change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer doesn't move.
  - The machine doesn't answer to a remote machine's pings.
  - Other programs that are not related to MySQL don't behave correctly.
  - Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

  In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as `glibc`) are up to date.

  It's always good to use a machine with ECC memory to discover memory problems early.
- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.
- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See Section 5.11, “The MySQL Log Files”.
- If you don't think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.
- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.
- If the problem is some runaway process, you can always try to kill it. If it doesn't want to die, there is probably a bug in the operating system.

If after you have examined all other possibilities and you have concluded that the MySQL server or a MySQL client is causing the problem, it's time to create a bug report for our mailing list or our support team. In the bug report, try to give a very detailed description of how the system is behaving and what you think is happening. You should also state why you think that MySQL is causing the

problem. Take into consideration all the situations in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system doesn't work.” This doesn't provide us with any information about what could be the problem.

If a program fails, it's always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?
- Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.
- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?
- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.8, “How to Report Bugs or Problems”.

A.2. Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

A.2.1. `Access denied`

An `Access denied` error can have many causes. Often the problem is related to the MySQL accounts that the server allows client programs to use when connecting. See Section 5.7.8, “Causes of `Access denied` Errors”, and Section 5.7.2, “How the Privilege System Works”.

A.2.2. `Can't connect to [local] MySQL server`

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the filesystem (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you don't specify a hostname or if you specify the special hostname `localhost`.

If the MySQL server is running on Windows 9x or Me, you can connect only via TCP/IP. If the server is running on Windows NT, 2000, XP, or 2003 and is started with the `--enable-named-pipe` option, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you don't give a hostname when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that doesn't work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the hostname.

The error (2002) `Can't connect to ...` normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket filename or TCP/IP port number when trying to connect to the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps`

`xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.9.2.3, “Starting and Troubleshooting the MySQL Server”.

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket filename might be different in your setup. `host_ip` represents the IP number of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
shell> mysqladmin -h `hostname` --port=3306 version
shell> mysqladmin -h host_ip version
shell> mysqladmin --protocol=socket --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotes with the `hostname` command; these cause the output of `hostname` (that is, the current hostname) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the hostname of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Here are some reasons the `Can't connect to local MySQL server` error might occur:

- `mysqld` is not running. Check your operating system's process list to ensure the `mysqld` process is present.
- You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: Section A.2.2.1, “`Connection to MySQL Server Failing on Windows`”.
- You are running on a system that uses MIT-pthreads. If you are running on a system that doesn't have native threads, `mysqld` uses the MIT-pthreads package. See Section 2.1.1, “Operating Systems Supported by MySQL”. However, not all MIT-pthreads versions support Unix socket files. On a system without socket file support, you must always specify the hostname explicitly when connecting to the server. Try using this command to check the connection to the server:

  ```
  shell> mysqladmin -h `hostname` version
  ```

- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a `cron` job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the `cron` job to not remove `mysql.sock` or to place the socket file somewhere else. See Section A.4.5, “How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`”.
- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket pathname for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

  ```
  shell> netstat -ln | grep mysql
  ```

  See Section A.4.5, “How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`”.
- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill` or with the `mysql_zap` script) before you can restart the MySQL server. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.
- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access

privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket` option that specifies a socket filename in a directory where the server can create it and where client programs can access it.

If you get the error message `Can't connect to MySQL server on some_host`, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.
- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)
- Make sure that your `mysqld` server was not started with the `--skip-networking` option. If it was, you cannot connect to it using TCP/IP.
- Check to make sure that there is no firewall blocking access to MySQL. Applications such as ZoneAlarm and the Windows XP personal firewall may need to be configured to allow external access to a MySQL server.

A.2.2.1. Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a `Can't connect to MySQL server` error, the reason might be that Windows doesn't allow for enough ephemeral (short-lived) ports to serve those connections.

By default, Windows allows 5000 ephemeral (short-lived) TCP ports to the user. After any port is closed it will remain in a `TIME_WAIT` status for 120 seconds. This status allows the connection to be reused at a much lower cost than reinitializing a brand new connection. However, the port will not be available again until this time expires.

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

IMPORTANT: The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, view the following article in the Microsoft Knowledge Base: http://support.microsoft.com/kb/256986/EN-US/.

1. Start Registry Editor (`Regedt32.exe`).
2. Locate the following key in the registry:

   ```
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
   ```

3. On the Edit menu, click Add Value, and then add the following registry value:

   ```
   Value Name: MaxUserPort
   Data Type: REG_DWORD
   Value: 65534
   ```

   This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the Edit menu, click Add Value, and then add the following registry value:

   ```
   Value Name: TcpTimedWaitDelay
   Data Type: REG_DWORD
   Value: 30
   ```

   This sets the number of seconds to hold a TCP port connection in TIME_WAIT state before closing. The valid range is between 0 (zero) and 300 (decimal). The default value is 0x78 (120 decimal).

5. Quit Registry Editor.

6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you've created.

A.2.3. Client does not support authentication protocol

MySQL 5.1 uses an authentication protocol based on a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. If you upgrade the server from 4.1, attempts to connect to it with an older client may fail with the following message:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

To solve this problem, you should use one of the following approaches:

- Upgrade all client programs to use a 4.1.1 or newer client library.
- When connecting to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.
- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the SET PASSWORD statement and the OLD_PASSWORD() function:

  ```
  mysql> SET PASSWORD FOR
      -> 'some_user'@'some_host' = OLD_PASSWORD('newpwd');
  ```

  Alternatively, use UPDATE and FLUSH PRIVILEGES:

  ```
  mysql> UPDATE mysql.user SET Password = OLD_PASSWORD('newpwd')
      -> WHERE Host = 'some_host' AND User = 'some_user';
  mysql> FLUSH PRIVILEGES;
  ```

Substitute the password you want to use for "*newpwd*" in the preceding examples. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm:

  1. Start `mysqld` with the `--old-passwords` option.

  2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

     ```
     mysql> SELECT Host, User, Password FROM mysql.user
         -> WHERE LENGTH(Password) > 16;
     ```

     For each account record displayed by the query, use the `Host` and `User` values and assign a password using the `OLD_PASSWORD()` function and either `SET PASSWORD` or `UPDATE`, as described earlier.

Note: In older versions of PHP, the `mysql` extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish to use the `mysql` extension with MySQL 4.1 or newer, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for "MySQL, Improved"; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done in order to use this MySQL client library. For more information about the `mysqli` extension, see http://php.net/mysqli.

It may also be possible to compile the older `mysql` extension against the new MySQL client library. This is beyond the scope of this Manual; consult the PHP documentation for more information. You also be able to obtain assistance with these issues in our MySQL with PHP forum [http://forums.mysql.com/list.php?52].

For additional background on password hashing and authentication, see Section 5.7.9, "Password Hashing in MySQL 4.1".

A.2.4. Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

A.2.5. Host '*host_name*' is blocked

If you get the following error, it means that `mysqld` has received many connect requests from the host '*host_name*' that have been interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The number of interrupted connect requests allowed is determined by the value of the

max_connect_errors system variable. After max_connect_errors failed requests, mysqld assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you execute a mysqladmin flush-hosts command or issue a FLUSH HOSTS statement. See Section 5.3.3, “Server System Variables”.

By default, mysqld blocks a host after 10 connection errors. You can adjust the value by starting the server like this:

```
shell> mysqld_safe --max_connect_errors=10000 &
```

If you get this error message for a given host, you should first verify that there isn't anything wrong with TCP/IP connections from that host. If you are having network problems, it does you no good to increase the value of the max_connect_errors variable.

A.2.6. Too many connections

If you get a Too many connections error when you try to connect to the mysqld server, this means that all available connections are in use by other clients.

The number of connections allowed is controlled by the max_connections system variable. Its default value is 100. If you need to support more connections, you should restart mysqld with a larger value for this variable.

mysqld actually allows max_connections+1 clients to connect. The extra connection is reserved for use by accounts that have the SUPER privilege. By granting the SUPER privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use SHOW PROCESSLIST to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.5.4.16, “SHOW PROCESSLIST Syntax”.

The maximum number of connections MySQL can support depends on the quality of the thread library on a given platform. Linux or Solaris should be able to support 500-1000 simultaneous connections, depending on how much RAM you have and what your clients are doing. Static Linux binaries provided by MySQL AB can support up to 4000 connections.

A.2.7. Out of memory

If you issue a query using the mysql client program and receive an error like the following one, it means that mysql does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke mysql with the --quick option. This causes it to use the mysql_use_result() C API function to retrieve the result set, which places less of a load on the client (but more on the server).

A.2.8. MySQL server has gone away

This section also covers the related Lost connection to server during query error.

The most common reason for the MySQL server has gone away error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent):

Error Code	Description
CR_SERVER_GONE_ERROR	The client couldn't send a question to the server.
CR_SERVER_LOST	The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start `mysqld`. See Section 5.3.3, “Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the `mysql` command-line client).

Some other common reasons for the `MySQL server has gone away` error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysqladmin kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- You got a timeout from the TCP/IP connection on the client side. This may happens if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
- You are using a windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

  The problem on windows is that in some cases MySQL doesn't get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from connection.

  In this case, even if the `reconnect` flag in the `MYSQL` structure is equal to 1, MySQL does not automatically reconnect and re-issue the query as it doesn't know if the server did get the original query or not.

  The solution to this is to either do a `mysql_ping` on the connection if there has been a long time since the last query (this is what `MyODBC` does) or set `wait_timeout` on the `mysqld` server so high that it in practice never times out.
- You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big `BLOB` columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 1MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section A.2.9, “`Packet too large`”.
- You also get a lost connection if you are sending a packet 16MB or larger if your client is older than 4.0.8 and your server is 4.0.8 and above, or the other way around.
- You may also see the `MySQL server has gone away` error if MySQL is started with the `--skip-networking` option.
- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server's uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

You can get more information about the lost connections by starting mysqld with the -

`-log-warnings=2` option. This logs some of the disconnected errors in the `hostname.err` file. See Section 5.11.1, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether or not the MySQL server died. You can find information about this in the server error log. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.
- If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.
- What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)
- Have you tried to run `mysqld` with the `--log` option to determine whether the problem query appears in the log?

See also Section A.2.10, “Communication Errors and Aborted Connections”, and Section 1.8, “How to Report Bugs or Problems”.

A.2.9. `Packet too large`

A communication packet is a single SQL statement sent to the MySQL server or a single row that is sent to the client.

The largest possible packet that can be transmitted to or from a MySQL 5.1 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues a `Packet too large` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
mysql> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 1MB. You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```
mysql> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of

memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

A.2.10. Communication Errors and Aborted Connections

The server error log can be a useful source of information about connection problems. See Section 5.11.1, “The Error Log”. If you start the server with the `--log-warnings` option, you might find messages like this in your error log:

```
010301 14:38:23  Aborted connection 854 to db: 'users' user: 'josh'
```

If `Aborted connections` messages appear in the error log, the cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.3.3, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

When any of these things happen, the server increments the `Aborted_clients` status variable.

The server increments the `Aborted_connects` status variable when the following things happen:

- A client doesn't have privileges to connect to a database.
- A client uses an incorrect password.
- A connection packet doesn't contain the right information.
- It takes more than `connect_timeout` seconds to get a connect packet. See Section 5.3.3, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server!

Other reasons for problems with aborted clients or aborted connections:

- Use of Ethernet protocol with Linux, both half and full duplex. Many Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file via FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. The only solution is switching the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and testing the results to determine the best setting.
- Some problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section A.2.9, “`Packet too large`”.

See also Section A.2.8, “`MySQL server has gone away`”.

A.2.11. `The table is full`

There are several ways a full-table error can occur:

- You are using a MySQL server older than 3.23 and an in-memory temporary table becomes larger than `tmp_table_size` bytes. To avoid this problem, you can use the `-O tmp_table_size=`*`val`* option to make `mysqld` increase the temporary table size or use the SQL option `SQL_BIG_TABLES` before you issue the problematic query. See Section 13.5.3, “`SET` Syntax”.

  You can also start `mysqld` with the `--big-tables` option. This is exactly the same as using `SQL_BIG_TABLES` for all queries.

  As of MySQL 3.23, this problem should not occur. If an in-memory temporary table becomes larger than `tmp_table_size`, the server automatically converts it to a disk-based `MyISAM` table.

- You are using `InnoDB` tables and run out of room in the `InnoDB` tablespace. In this case, the solution is to extend the `InnoDB` tablespace. See Section 15.2.7, “Adding and Removing `InnoDB` Data and Log Files”.

- You are using `ISAM` or `MyISAM` tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.

- You are using a `MyISAM` table and the space required for the table exceeds what is allowed by the internal pointer size. If you don't specify the `MAX_ROWS` table option when you create a table, MySQL uses the `myisam_data_pointer_size` system variable. The default value is 6 bytes, which is enough to allow 256TB of data. See Section 5.3.3, “Server System Variables”.

  You can check the maximum data/index sizes by using this statement:

  ```
  SHOW TABLE STATUS FROM database LIKE 'tbl_name';
  ```

  You also can use `myisamchk -dv /path/to/table-index-file`.

  If the pointer size is too small, you can fix the problem by using `ALTER TABLE`:

  ```
  ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
  ```

  You have to specify `AVG_ROW_LENGTH` only for tables with `BLOB` or `TEXT` columns; in this case, MySQL can't optimize the space required based only on the number of rows.

A.2.12. `Can't create/write to file`

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` sec-

tion of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.3.2, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the filesystem is full:

```
shell> perror 28
Error code  28:  No space left on device
```

A.2.13. Commands out of sync

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

A.2.14. Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

`Found wrong password for user '`*`some_user`*`'@'`*`some_host`*`'; ignoring user`

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. You can check this by executing `mysqlshow mysql user` to see whether the `Password` column is shorter than 16 characters. If so, you can correct this condition by running the `scripts/add_long_password` script.
- The account has an old password (eight characters long) and you didn't start `mysqld` with the `--old-protocol` option. Update the account in the `user` table to have a new password or restart `mysqld` with the `--old-protocol` option.
- You have specified a password in the `user` table without using the `PASSWORD()` function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD()` function:

  ```
  mysql> UPDATE user SET Password=PASSWORD('newpwd')
      -> WHERE User='some_user' AND Host='some_host';
  ```

A.2.15. Table '*tbl_name*' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database

with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a filesystem that has case-sensitive filenames.
- Even for filesystems that are not case sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 13.5.4, "`SHOW` Syntax".

A.2.16. `Can't initialize character set`

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multi-byte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running `configure` with the `--with-charset=charset_name` or `--with-extra-charsets=charset_name` option. See Section 2.8.2, "Typical `configure` Options".

  All standard MySQL binaries are compiled with `--with-extra-character-sets=complex`, which enables support for all multi-byte character sets. See Section 5.10.1, "The Character Set Used for Data and Sorting".

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

  In this case, you need to use one of the following methods to solve the problem:

  - Recompile the client with support for the character set. See Section 2.8.2, "Typical `configure` Options".
  - Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.
  - Copy the character definition files to the path where the client expects them to be.

A.2.17. File Not Found

If you get `ERROR '...' not found (errno: 23)`, `Can't open file: ... (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you haven't allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```
shell> perror 23
Error code  23:  File table overflow
shell> perror 24
Error code  24:  Too many open files
```

```
shell> perror 11
Error code  11:  Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_open_cache` system variable (the default value is 64). Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysqld_safe` or (as of MySQL 3.23.30) set the `open_files_limit` system variable. See Section 5.3.3, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 4.3.2, “Using Option Files”. If you have an old version of `mysqld` that doesn't support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the ‘#’ character to uncomment this line, and change the number `256` to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

Note: If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

A.3. Installation-Related Issues

A.3.1. Problems Linking to the MySQL Client Library

When you are linking an application program to use the MySQL client library, you might get undefined reference errors for symbols that start with `mysql_`, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x57): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x69): undefined reference to `mysql_error'
/tmp/ccFKsdPa.o(.text+0x9a): undefined reference to `mysql_close'
```

You should be able to solve this problem by adding `-Ldir_path -lmysqlclient` at the end of your link command, where `dir_path` represents the pathname of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from `mysql_config` might indicate other libraries that should be specified on the link command as well.

If you get `undefined reference` errors for the `uncompress` or `compress` function, add `-lz` to the end of your link command and try again.

If you get `undefined reference` errors for a function that should exist on your system, such as `connect`, check the manual page for the function in question to determine which libraries you should add to the link command.

You might get `undefined reference` errors such as the following for functions that don't exist

on your system:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

This usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours. In this case, you should download the latest MySQL source distribution and compile MySQL yourself. See Section 2.8, “MySQL Installation Using a Source Distribution”.

You might get undefined reference errors at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `mysqlclient` library can't be found, it means that your system can't find the shared `libmysqlclient.so` library. The fix for this is to tell your system to search for shared libraries where the library is located. Use whichever of the following methods is appropriate for your system:

- Add the path to the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` environment variable.
- Add the path to the directory where `libmysqlclient.so` is located to the `LD_LIBRARY` environment variable.
- Copy `libmysqlclient.so` to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`.

Another way to solve this problem is by linking your program statically with the `-static` option, or by removing the dynamic MySQL libraries before linking your code. Before trying the second method, you should be sure that no other programs are using the dynamic libraries.

A.3.2. How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. In order to change `mysqld` to run as a normal unprivileged Unix user *`user_name`*, you must do the following:

1. Stop the server if it's running (use `mysqladmin shutdown`).
2. Change the database directories and files so that *`user_name`* has privileges to read and write files in them (you might need to do this as the Unix `root` user):

   ```
   shell> chown -R user_name /path/to/mysql/datadir
   ```

   If you do not do this, the server is not able to access databases or tables when it runs as *`user_name`*.

   If directories or files within the MySQL data directory are symbolic links, you'll also need to follow those links and change the directories and files they point to. `chown -R` might not follow symbolic links for you.
3. Start the server as user *`user_name`*. If you are using MySQL 3.22 or later, another alternative is to start `mysqld` as the Unix `root` user and use the `--user=`*`user_name`* option. `mysqld` starts up, then switches to run as the Unix user *`user_name`* before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the username by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

   ```
   [mysqld]
   ```

```
user=user_name
```

If your Unix machine itself isn't secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.9, “Post-Installation Setup and Testing”.

A.3.3. Problems with File Permissions

If you have problems with file permissions, the `UMASK` environment variable might be set incorrectly when `mysqld` starts. For example, MySQL might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` value is `0660`. You can change this behavior by starting `mysqld_safe` as follows:

```
shell> UMASK=384  # = 600 in octal
shell> export UMASK
shell> mysqld_safe &
```

By default, MySQL creates database and `RAID` directories with an access permission value of `0700`. You can modify this behavior by setting the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, if you want to give group access to all new directories, you can do this:

```
shell> UMASK_DIR=504  # = 770 in octal
shell> export UMASK_DIR
shell> mysqld_safe &
```

In MySQL 3.23.25 and above, MySQL assumes that the value for `UMASK` and `UMASK_DIR` is in octal if it starts with a zero.

See Appendix F, *Environment Variables*.

A.4. Administration-Related Issues

A.4.1. How to Reset the Root Password

If you have never set a `root` password for MySQL, the server does not require a password at all for connecting as `root`. However, it is recommended to set a password for each account. See Section 5.6.1, “General Security Guidelines”.

If you set a `root` password previously, but have forgotten what it was, you can set a new password. The following procedure is for Windows systems. The procedure for Unix systems is given later in this section.

The procedure under Windows:

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager:

```
Start Menu -> Control Panel -> Administrative Tools -> Services
```

Then find the MySQL service in the list, and stop it.

If your server is not running as a service, you may need to use the Task Manager to force it to stop.

3. Create a text file and place the following command within it on a single line:

```
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPassword');
```

Save the file with any name. For this example the file will be `C:\mysql-init.txt`.

4. Open a console window to get to the DOS command prompt:

```
Start Menu -> Run -> cmd
```

5. We are assuming that you installed MySQL to `C:\mysql`. If you installed MySQL to another location, adjust the following commands accordingly.

At the DOS command prompt, execute this command:

```
C:\> C:\mysql\bin\mysqld-nt --init-file=C:\mysql-init.txt
```

The contents of the file named by the `--init-file` option are executed at server startup, changing the `root` password. After the server has started successfully, you should delete `C:\mysql-init.txt`.

If you install MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` option:

```
C:\> C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld-nt.exe
         --defaults-file="C:\Program Files\MySQL\MySQL Server 5.1\my.ini"
         --init-file=C:\mysql-init.txt
```

The appropriate `--defaults-file` setting can be found using the Services Manager:

```
Start Menu -> Control Panel -> Administrative Tools -> Services
```

Find the MySQL service in the list, right-click on it, and choose the `Properties` option. The `Path to executable` field contains the `--defaults-file` setting.

6. Stop the MySQL server, then restart it in normal mode again. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

7. You should be able to connect using the new password.

In a Unix environment, the procedure for resetting the `root` password is as follows:

1. Log on to your system as either the Unix `root` user or as the same user that the `mysqld` server runs as.

2. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, hostname, and configuration. Common locations are `/var/lib/mysql/`, `/var/run/mysqld/`, and `/usr/local/mysql/data/`. Generally, the filename has the extension of `.pid` and begins with either `mysqld` or your system's

hostname.

You can stop the MySQL server by sending a normal `kill` (not `kill -9`) to the `mysqld` process, using the pathname of the `.pid` file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Note the use of backticks rather than forward quotes with the `cat` command; these cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file and place the following command within it on a single line:

   ```
   SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPassword');
   ```

   Save the file with any name. For this example the file will be `~/mysql-init`.

4. Restart the MySQL server with the special `--init-file=~/mysql-init` option:

   ```
   shell> mysqld_safe --init-file=~/mysql-init &
   ```

   The contents of the init-file are executed at server startup, changing the root password. After the server has started successfully you should delete `~/mysql-init`.

5. You should be able to connect using the new password.

Alternatively, on any platform, you can set the new password using the `mysql` client(but this approach is less secure):

1. Stop `mysqld` and restart it with the `--skip-grant-tables --user=root` options (Windows users omit the `--user=root` portion).

2. Connect to the `mysqld` server with this command:

   ```
   shell> mysql -u root
   ```

3. Issue the following statements in the `mysql` client:

   ```
   mysql> UPDATE mysql.user SET Password=PASSWORD('newpwd')
       ->                   WHERE User='root';
   mysql> FLUSH PRIVILEGES;
   ```

   Replace "*newpwd*" with the actual `root` password that you want to use.

4. You should be able to connect using the new password.

A.4.2. What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This doesn't mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqladmin version`. If `mysqld` has died and restarted, you may find the reason by looking in the server's error log. See Section 5.11.1, "The Error Log".

On some systems, you can find in the error log a stack trace of where `mysqld` died that you can resolve with the `resolve_stack_dump` program. See Section E.1.4, “Using a Stack Trace”. Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with `--delay-key-write`, in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `--flush` option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that doesn't support good filesystem locks (normally handled by the `lockd` lock manager), or you are running multiple servers with the `--skip-external-locking` option.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.
- You have found a bug in the data storage code. This isn't likely, but it's at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Please try the following things:

- Stop the `mysqld` server with `mysqladmin shutdown`, run `myisamchk --silent --force */*.MYI` from the data directory to check all `MyISAM` tables, and restart `mysqld`. This ensures that you are running from a clean state. See Chapter 5, *Database Administration*.
- Start `mysqld` with the `--log` option and try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.11.2, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have been able to locate the bug and should submit a bug report for it. See Section 1.8, “How to Report Bugs or Problems”.
- Try to make a test case that we can use to repeat the problem. See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.
- Try running the tests in the `mysql-test` directory and the MySQL benchmarks. See Section 27.1.2, “MySQL Test Suite”. They should test MySQL rather well. You can also add code to the benchmarks that simulates your application. The benchmarks can be found in the `sql-bench` directory in a source distribution or, for a binary distribution, in the `sql-bench` directory under your MySQL installation directory.
- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)
- If you configure MySQL for debugging, it is much easier to gather information about possible errors if something goes wrong. Configuring MySQL for debugging causes a safe memory allocator to be included that can find some errors. It also provides a lot of output about what is hap-

pening. Reconfigure MySQL with the `--with-debug` or `--with-debug=full` option to `configure` and then recompile. See Section E.1, “Debugging a MySQL Server”.

- Make sure that you have applied the latest patches for your operating system.

- Use the `--skip-external-locking` option to `mysqld`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)

- Have you tried `mysqladmin -u root processlist` when `mysqld` appears to be running but not responding? Sometimes `mysqld` is not comatose even though you might think so. The problem may be that all connections are in use, or there may be some internal lock problem. `mysqladmin -u root processlist` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

- Run the command `mysqladmin -i 5 status` or `mysqladmin -i 5 -r status` in a separate window to produce statistics while you run your other queries.

- Try the following:

  1. Start `mysqld` from `gdb` (or another debugger). See Section E.1.3, “Debugging `mysqld` under `gdb`”.

  2. Run your test scripts.

  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

     ```
     backtrace
     info local
     up
     info local
     up
     info local
     ```

     With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where *`N`* is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to crash or misbehave.

- Send a normal bug report. See Section 1.8, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, it may be that the crash results from something that exists only on your computer (for example, an error that is related to your particular system libraries).

- If you have a problem with tables containing dynamic-length rows and you are using only `VARCHAR` columns (not `BLOB` or `TEXT` columns), you can try to change all `VARCHAR` to `CHAR` with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

  The current dynamic row code has been in use at MySQL AB for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Do not rule out your server hardware when diagnosing problems. Defective hardware can be the cause of data corruption. Particular attention should be paid to both RAMS and hard-drives when troubleshooting hardware.

A.4.3. How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to `MyISAM` tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event”.

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.
- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, you can take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- To abort the thread, you must use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition allows the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA INFILE` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

A.4.4. Where MySQL Stores Temporary Files

MySQL uses the value of the `TMPDIR` environment variable as the pathname of the directory in which to store temporary files. If you don't have `TMPDIR` set, MySQL uses the system default, which is normally `/tmp`, `/var/tmp`, or `/usr/tmp`. If the filesystem containing your temporary file directory is too small, you can use the `--tmpdir` option to `mysqld` to specify a directory in a filesystem where you have enough space.

In MySQL 5.1, the `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (‘`:`’) on Unix and semicolon characters (‘`;`’) on Windows, NetWare, and OS/2. **Note**: To spread the load effectively, these paths should be located on different *physical* disks, not different partitions of the same disk.

If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

MySQL creates all temporary files as hidden files. This ensures that the temporary files are removed if `mysqld` is terminated. The disadvantage of using hidden files is that you do not see a big temporary file that fills up the filesystem in which the temporary file directory is located.

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
* number of matched rows
* 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some `SELECT` queries, MySQL also creates temporary SQL tables. These are not hidden and have names of the form `SQL_*`.

`ALTER TABLE` creates a temporary table in the same directory as the original table.

A.4.5. How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. This might cause problems, because on some versions of Unix, anyone can delete files in the `/tmp` directory.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

  ```
  [mysqld]
  socket=/path/to/socket

  [client]
  socket=/path/to/socket
  ```

  See Section 4.3.2, “Using Option Files”.

- Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.

- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.

- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `--with-unix-socket-path` option when you run `configure`. See Section 2.8.2, “Typical `configure` Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

A.4.6. Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in GMT and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong value. This should be done for the environment in which the server runs; for example, in `mysqld_safe` or `mysql.server`. See Appendix F, *Environment Variables*.

You can set the time zone for the server with the `--timezone=`*`timezone_name`* option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The allowable values for `--timezone` or `TZ` are system-dependent. Consult your operating system documentation to see what values are acceptable.

A.5. Query-Related Issues

A.5.1. Case Sensitivity in Searches

By default, MySQL searches are not case sensitive (although there are some character sets that are never case insensitive, such as `czech`). This means that if you search with *`col_name`* `LIKE 'a%'`, you get all column values that start with `A` or `a`. If you want to make this search case sensitive, make sure that one of the operands has a case sensitive or binary collation. For example, if you are comparing a column and a string that both have the `latin1` character set, you can use the `COLLATE` operator to cause either operand to have the `latin1_general_cs` or `latin1_bin` collation. For example:

```
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case sensitive or binary collation. See Section 13.1.5, “`CREATE TABLE` Syntax”.

Simple comparison operations (`>=, >, =, <, <=`, sorting, and grouping) are based on each character's “sort value.” Characters with the same sort value (such as ‘`E`’, ‘`e`’, and ‘`Ã©`’) are treated as the same character.

A.5.2. Problems Using `DATE` Columns

The format of a `DATE` value is `'YYYY-MM-DD'`. According to standard SQL, no other format is allowed. You should use this format in `UPDATE` expressions and in the `WHERE` clause of `SELECT` statements. For example:

```
mysql> SELECT * FROM tbl_name WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context (and vice versa). It is also smart enough to allow a “relaxed” string form when updating and in a `WHERE` clause that compares a date to a `TIMESTAMP`, `DATE`, or `DATETIME` column. (“Relaxed form” means that any punctuation character may be used as the separator between parts. For example, `'2004-08-15'` and `'2004#08#15'` are equivalent.) MySQL can also convert a string containing no separators (such as `'20040815'`), provided it makes sense as a date.

When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` to a constant string with the `<`, `<=`, `=`, `>=`, `>`, or `BETWEEN` operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns

- When you compare a DATE, TIME, DATETIME, or TIMESTAMP column to an expression
- When you use any other comparison method than those just listed, such as IN or STRCMP().

For these exceptional cases, the comparison is done by converting the objects to strings and performing a string comparison.

To keep things safe, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special date '0000-00-00' can be stored and retrieved as '0000-00-00'. When using a '0000-00-00' date through MyODBC, it is automatically converted to NULL in MyODBC 2.50.12 and above, because ODBC can't handle this kind of date.

Because MySQL performs the conversions described above, the following statements work:

```
mysql> INSERT INTO tbl_name (idate) VALUES (19970505);
mysql> INSERT INTO tbl_name (idate) VALUES ('19970505');
mysql> INSERT INTO tbl_name (idate) VALUES ('97-05-05');
mysql> INSERT INTO tbl_name (idate) VALUES ('1997.05.05');
mysql> INSERT INTO tbl_name (idate) VALUES ('1997 05 05');
mysql> INSERT INTO tbl_name (idate) VALUES ('0000-00-00');

mysql> SELECT idate FROM tbl_name WHERE idate >= '1997-05-05';
mysql> SELECT idate FROM tbl_name WHERE idate >= 19970505;
mysql> SELECT MOD(idate,100) FROM tbl_name WHERE idate >= 19970505;
mysql> SELECT idate FROM tbl_name WHERE idate >= '19970505';
```

However, the following does not work:

```
mysql> SELECT idate FROM tbl_name WHERE STRCMP(idate,'20030505')=0;
```

STRCMP() is a string function, so it converts idate to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you are using the ALLOW_INVALID_DATES SQL mode, MySQL allows you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12.

This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

If you are not using the NO_ZERO_IN_DATE SQL mode, the day or month part can be zero. This is convenient if you want to store a birthdate in a DATE column and you know only part of the date.

If you are not using the NO_ZERO_DATE SQL mode, MySQL also allows you to store '0000-00-00' as a "dummy date." This is in some cases more convenient than using NULL values.

If the date cannot be converted to any reasonable value, a 0 is stored in the DATE column, which is retrieved as '0000-00-00'. This is both a speed and a convenience issue. We believe that the database server's responsibility is to retrieve the same date you stored (even if the data was not logically correct in all cases). We think it is up to the application and not the server to check the dates.

If you want MySQL to check all dates and accept only legal dates (unless overridden by IGNORE), you should set sql_mode to "NO_ZERO_IN_DATE,NO_ZERO_DATE".

A.5.3. Problems with NULL Values

The concept of the NULL value is a common source of confusion for newcomers to SQL, who often

think that NULL is the same thing as an empty string ''. This is not the case. For example, the following statements are completely different:

```
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the phone column, but the first inserts a NULL value and the second inserts an empty string. The meaning of the first can be regarded as "phone number is not known" and the meaning of the second can be regarded as "the person is known to have no phone, and thus no phone number."

To help with NULL handling, you can use the IS NULL and IS NOT NULL operators and the IFNULL() function.

In SQL, the NULL value is never true in comparison to any other value, even NULL. An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return NULL:

```
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

If you want to search for column values that are NULL, you cannot use an expr = NULL test. The following statement returns no rows, because expr = NULL is never true for any expression:

```
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for NULL values, you must use the IS NULL test. The following statements show how to find the NULL phone number and the empty phone number:

```
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, "Working with NULL Values", for additional information and examples.

You can add an index on a column that can have NULL values if you are using the MyISAM, InnoDB, or BDB, or MEMORY storage engine. Otherwise, you must declare an indexed column NOT NULL, and you cannot insert NULL into the column.

When reading data with LOAD DATA INFILE, empty or missing columns are updated with ''. If you want a NULL value in a column, you should use \N in the data file. The literal word "NULL" may also be used under some circumstances. See Section 13.2.5, "LOAD DATA INFILE Syntax".

When using DISTINCT, GROUP BY, or ORDER BY, all NULL values are regarded as equal.

When using ORDER BY, NULL values are presented first, or last if you specify DESC to sort in descending order.

Aggregate (summary) functions such as COUNT(), MIN(), and SUM() ignore NULL values. The exception to this is COUNT(*), which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-NULL values in the age column:

```
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles NULL values specially. If you insert NULL into a TIMESTAMP column, the current date and time is inserted. If you insert NULL into an integer column that has the AUTO_INCREMENT attribute, the next number in the sequence is inserted.

A.5.4. Problems with Column Aliases

You can use an alias to refer to a column in GROUP BY, ORDER BY, or HAVING clauses. Aliases can also be used to give columns better names:

```
SELECT SQRT(a*b) AS root FROM tbl_name GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL doesn't allow you to refer to a column alias in a WHERE clause. This restriction is imposed because when the WHERE code is executed, the column value may not yet be determined. For example, the following query is illegal:

```
SELECT id, COUNT(*) AS cnt FROM tbl_name WHERE cnt > 0 GROUP BY id;
```

The WHERE statement is executed to determine which rows should be included in the GROUP BY part, whereas HAVING is used to decide which rows from the result set should be used.

A.5.5. Rollback Failure for Non-Transactional Tables

If you receive the following message when trying to perform a ROLLBACK, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These non-transactional tables are not affected by the ROLLBACK statement.

If you were not deliberately mixing transactional and non-transactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your mysqld server (or that was disabled with a startup option). If mysqld doesn't support a storage engine, it instead creates the table as a MyISAM table, which is non-transactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.5.4.18, “SHOW TABLE STATUS Syntax”, and Section 13.5.4.5, “SHOW CREATE TABLE Syntax”.

You can check which storage engines your mysqld server supports by using this statement:

```
SHOW ENGINES;
```

You can also use the following statement, and check the value of the variable that is associated with the storage engine in which you are interested:

```
SHOW VARIABLES LIKE 'have_%';
```

For example, to determine whether the InnoDB storage engine is available, check the value of the have_innodb variable.

See Section 13.5.4.8, “SHOW ENGINES Syntax”, and Section 13.5.4.21, “SHOW VARIABLES Syntax”.

A.5.6. Deleting Rows from Related Tables

If the total length of the DELETE statement for related_table is more than 1MB (the default value of the max_allowed_packet system variable), you should split it into smaller parts and

execute multiple DELETE statements. You probably get the fastest DELETE by specifying only 100 to 1,000 related_column values per statement if the related_column is indexed. If the related_column isn't indexed, the speed is independent of the number of arguments in the IN clause.

A.5.7. Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that doesn't return any rows, you should use the following procedure to find out what is wrong:

1. Test the query with EXPLAIN to check whether you can find something that is obviously wrong. See Section 7.2.1, "EXPLAIN Syntax (Get Information About a SELECT)".

2. Select only those columns that are used in the WHERE clause.

3. Remove one table at a time from the query until it returns some rows. If the tables are large, it's a good idea to use LIMIT 10 with the query.

4. Issue a SELECT for the column that should have matched a row against the table that was last removed from the query.

5. If you are comparing FLOAT or DOUBLE columns with numbers that have decimals, you can't use equality (=) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the FLOAT to a DOUBLE fixes this. See Section A.5.8, "Problems with Floating-Point Comparisons".

6. If you still can't figure out what's wrong, create a minimal test that can be run with mysql test < query.sql that shows your problems. You can create a test file by dumping the tables with mysqldump --quick db_name *tbl_name_1 ... tbl_name_n* > query.sql. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your SELECT statement at the end of the file.

   Verify that the test file demonstrates the problem by executing these commands:

   ```
   shell> mysqladmin create test2
   shell> mysql test2 < query.sql
   ```

   Attach the test file to a bug report, which you can file using the instructions in Section 1.8, "How to Report Bugs or Problems".

A.5.8. Problems with Floating-Point Comparisons

Note that the following section is relevant primarily to working with DOUBLE and FLOAT columns, due to the inexact nature of floating point numbers. MySQL performs DECIMAL operations with a precision of 64 decimal digits, which should solve most common inaccuracy problems when it comes to DECIMAL columns.

Floating-point numbers sometimes cause confusion because they are not stored as exact values inside computer architecture. What you can see on the screen usually is not the exact value of the number. The data types FLOAT and DOUBLE are such. DECIMAL columns store values with exact precision because they are represented as strings.

The following example demonstrates the problem using DOUBLE:

```
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
    -> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
    -> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
    -> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
    -> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
```

```
    -> (6, 0.00, 0.00), (6, -51.40, 0.00);

mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
    -> FROM t1 GROUP BY i HAVING a <> b;

+------+-------+------+
| i    | a     | b    |
+------+-------+------+
|    1 |  21.4 | 21.4 |
|    2 |  76.8 | 76.8 |
|    3 |   7.4 |  7.4 |
|    4 |  15.4 | 15.4 |
|    5 |   7.2 |  7.2 |
|    6 | -51.4 |    0 |
+------+-------+------+
```

The result is correct. Although the first five records look like they shouldn't pass the comparison test (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on computer architecture.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row — the last one shown above.

A.6. Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL doesn't have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

  ```
  mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
  ```

  `EXPLAIN` is discussed in more detail in Section 7.2.1, “`EXPLAIN` Syntax (Get Information About a `SELECT`)”.

- Use `ANALYZE TABLE` *`tbl_name`* to update the key distributions for the scanned table. See Section 13.5.2.1, “`ANALYZE TABLE` Syntax”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index. See Section 13.2.7, “`SELECT` Syntax”.

  ```
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name=t2.col_name;
  ```

  `USE INDEX` and `IGNORE INDEX` may also be useful.

- Global and table-level `STRAIGHT_JOIN`. See Section 13.2.7, “`SELECT` Syntax”.

- You can tune global or thread-specific system variables. For example, Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.3.3, “Server System Variables”.

A.7. Table Definition-Related Issues

A.7.1. Problems with ALTER TABLE

`ALTER TABLE` changes a table to the current character set. If you get a duplicate-key error during `ALTER TABLE`, the cause is either that the new character sets maps two keys to the same value or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm'
to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`. (You may want to move them elsewhere instead of deleting them.)

`ALTER TABLE` works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use `ALTER TABLE` on a transactional table or if you are using Windows or OS/2, `ALTER TABLE` unlocks the table if you had done a `LOCK TABLE` on it. This is done because `InnoDB` and these operating systems cannot drop a table that is in use.

A.7.2. How to Change the Order of Columns in a Table

First, consider whether you really need to change the column order in a table. The whole point of SQL is to abstract the application from the data storage format. You should always specify the order in which you wish to retrieve your data. The first of the following statements returns columns in the order *`col_name1`*, *`col_name2`*, *`col_name3`*, whereas the second returns them in the order *`col_name1`*, *`col_name3`*, *`col_name2`*:

```
mysql> SELECT col_name1, col_name2, col_name3 FROM tbl_name;
mysql> SELECT col_name1, col_name3, col_name2 FROM tbl_name;
```

If you decide to change the order of table columns anyway, you can do so as follows:

1. Create a new table with the columns in the new order.
2. Execute this statement:

   ```
   mysql> INSERT INTO new_table
       -> SELECT columns-in-new-order FROM old_table;
   ```

3. Drop or rename `old_table`.
4. Rename the new table to the original name:

```
mysql> ALTER TABLE new_table RENAME old_table;
```

`SELECT *` is quite suitable for testing queries. However, in an application, you should *never* rely on using `SELECT *` and retrieving the columns based on their position. The order and position in which columns are returned does not remain the same if you add, move, or delete columns. A simple change to your table structure could cause your application to fail.

A.7.3. TEMPORARY TABLE Problems

The following list indicates limitations on the use of `TEMPORARY` tables:

- A `TEMPORARY` table can only be of type `HEAP`, `ISAM`, `MyISAM`, `MERGE`, or `InnoDB`.
- You cannot refer to a `TEMPORARY` table more than once in the same query. For example, the following does not work:

  ```
  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can't reopen table: 'temp_table'
  ```

- The `SHOW TABLES` statement does not list `TEMPORARY` tables.
- You cannot use `RENAME` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` instead:

  ```
  mysql> ALTER TABLE orig_name RENAME new_name;
  ```

- There are known issues in using temporary tables with replication. See Section 6.8, “Replication Features and Known Problems”, for more information.

A.8. Known Issues in MySQL

This section is a list of the known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and porting instructions in Section 2.12, “Operating System-Specific Notes”, and Appendix E, *Porting to Other Systems*.

A.8.1. Open Issues in MySQL

The following problems are known and fixing them is a high priority:

- If you compare a `NULL` value to a subquery using `ALL/ANY/SOME` and the subquery returns an empty result, the comparison might evaluate to the non-standard result of `NULL` rather than to `TRUE` or `FALSE`. This will be fixed in MySQL 5.1.
- Subquery optimization for `IN` is not as effective as for `=`.
- Even if you use `lower_case_table_names=2` (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function `DATABASE()` or within the various logs (on case-insensitive systems).
- Dropping a `FOREIGN KEY` constraint doesn't work in replication because the constraint may have another name on the slave.
- `REPLACE` (and `LOAD DATA` with the `REPLACE` option) does not trigger `ON DELETE CAS-`

CADE.

- DISTINCT with ORDER BY doesn't work inside GROUP_CONCAT() if you don't use all and only those columns that are in the DISTINCT list.

- If one user has a long-running transaction and another user drops a table that is updated in the transaction, there is small chance that the binary log may contain the DROP TABLE command before the table is used in the transaction itself. We plan to fix this by having the DROP TABLE command wait until the table is not being used in any transaction.

- When inserting a big integer value (between 2^{63} and 2^{64}–1) into a decimal or string column, it is inserted as a negative value because the number is evaluated in a signed integer context.

- FLUSH TABLES WITH READ LOCK does not block COMMIT if the server is running without binary logging, which may cause a problem (of consistency between tables) when doing a full backup.

- ANALYZE TABLE on a BDB table may in some cases make the table unusable until you restart mysqld. If this happens, look for errors of the following form in the MySQL error file:

  ```
  001207 22:07:56  bdb:  log_flush: LSN past current end-of-log
  ```

- Don't execute ALTER TABLE on a BDB table on which you are running multiple-statement transactions until all those transactions complete. (The transaction might be ignored.)

- ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE may cause problems on tables for which you are using INSERT DELAYED.

- Performing LOCK TABLE ... and FLUSH TABLES ... doesn't guarantee that there isn't a half-finished transaction in progress on the table.

- BDB tables are relatively slow to open. If you have many BDB tables in a database, it takes a long time to use the mysql client on the database if you are not using the -A option or if you are using rehash. This is especially noticeable when you have a large table cache.

- Replication uses query-level logging: The master writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases.

  It is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is non-deterministic (generally not a recommended practice, even outside of replication).

  For example:

  - CREATE ... SELECT or INSERT ... SELECT statements that insert zero or NULL values into an AUTO_INCREMENT column.

  - DELETE if you are deleting rows from a table that has foreign keys with ON DELETE CASCADE properties.

  - REPLACE ... SELECT, INSERT IGNORE ... SELECT if you have duplicate key values in the inserted data.

  If and only if the preceding queries have no ORDER BY clause guaranteeing a deterministic order.

  For example, for INSERT ... SELECT with no ORDER BY, the SELECT may return rows in a different order (which results in a row having different ranks, hence getting a different number in the AUTO_INCREMENT column), depending on the choices made by the optimizers on the master and slave.

  A query is optimized differently on the master and slave only if:

- The table is stored using a different storage engine on the master than on the slave. (It is possible to use different storage engines on the master and slave. For example, you can use `InnoDB` on the master, but `MyISAM` on the slave if the slave has less available disk space.)
- MySQL buffer sizes (`key_buffer_size`, and so on) are different on the master and slave.
- The master and slave run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using `mysqlbinlog|mysql`.

The easiest way to avoid this problem is to add an `ORDER BY` clause to the aforementioned non-deterministic queries to ensure that the rows are always stored or modified in the same order.

In future MySQL versions, we will automatically add an `ORDER BY` clause when needed.

The following issues are known and will be fixed in due time:

- Log filenames are based on the server hostname (if you don't specify a filename with the startup option). You have to use options such as `--log-bin=`*`old_host_name`*`-bin` if you change your hostname to something else. Another option is to rename the old files to reflect your hostname change (if these are binary logs, you need to edit the binary log index file and fix the binlog names there as well). See Section 5.3.1, "`mysqld` Command-Line Options".
- `mysqlbinlog` does not delete temporary files left after a `LOAD DATA INFILE` command. See Section 8.6, "mysqlbinlog — Utility for Processing Binary Log Files".
- `RENAME` doesn't work with `TEMPORARY` tables or tables used in a `MERGE` table.
- Due to the way table definition files are stored, you cannot use character 255 (`CHAR(255)`) in table names, column names, or enumerations. This is scheduled to be fixed in version 5.1 when we implement new table definition format files.
- When using `SET CHARACTER SET`, you can't use translated characters in database, table, and column names.
- You can't use '_' or '%' with `ESCAPE` in `LIKE ... ESCAPE`.
- If you have a `DECIMAL` column in which the same number is stored in different formats (for example, `+01.00`, `1.00`, `01.00`), `GROUP BY` may regard each value as a different value.
- You cannot build the server in another directory when using MIT-pthreads. Because this requires changes to MIT-pthreads, we are not likely to fix this. See Section 2.8.5, "MIT-pthreads Notes".
- `BLOB` and `TEXT` values can't reliably be used in `GROUP BY`, `ORDER BY` or `DISTINCT`. Only the first `max_sort_length` bytes are used when comparing `BLOB` values in these cases. The default value of `max_sort_length` is 1024 and can be changed at server startup time or at runtime.
- Numeric calculations are done with `BIGINT` or `DOUBLE` (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with `BIGINT` precision, `IF` and `ELT()` with `BIGINT` or `DOUBLE` precision, and the rest with `DOUBLE` precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.
- You can have up to 255 `ENUM` and `SET` columns in one table.
- In `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET`

columns by their string value rather than by the string's relative position in the set.

- `mysqld_safe` redirects all messages from `mysqld` to the `mysqld` log. One problem with this is that if you execute `mysqladmin refresh` to close and reopen the log, `stdout` and `stderr` are still redirected to the old log. If you use `--log` extensively, you should edit `mysqld_safe` to log to *`host_name`*`.err` instead of *`host_name`*`.log` so that you can easily reclaim the space for the old log by deleting it and executing `mysqladmin refresh`.

- In an `UPDATE` statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments `KEY` by `2`, **not** `1`:

  ```
  mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
  ```

- You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following doesn't work:

  ```
  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can't reopen table: 'temp_table'
  ```

- The optimizer may handle `DISTINCT` differently when you are using "hidden" columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns don't participate in the `DISTINCT` comparison. We will probably change this in the future to never compare the hidden columns when executing `DISTINCT`.

  An example of this is:

  ```
  SELECT DISTINCT mp3id FROM band_downloads
         WHERE userid = 9 ORDER BY id DESC;
  ```

  and

  ```
  SELECT DISTINCT band_downloads.mp3id
         FROM band_downloads,band_mp3
         WHERE band_downloads.userid = 9
         AND band_mp3.id = band_downloads.mp3id
         ORDER BY band_downloads.id DESC;
  ```

  In the second case, using MySQL Server 3.23.x, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

  Note that this happens only for queries where that do not have the `ORDER BY` columns in the result.

- If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.

- Creation of a table of type `MERGE` doesn't check whether the underlying tables are compatible types.

- If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

Appendix B. Error Codes and Messages

This chapter lists the errors that may appear when you call MySQL from any host language. The first list displays server error messages. The second list displays client program messages.

B.1. Server Error Codes and Messages

Server error information comes from the following source files:

- Error message information is listed in the `share/errmsg.txt` file. `%d` and `%s` represent numbers and strings, respectively, that are substituted into the Message values when they are displayed.
- The Error values listed in `share/errmsg.txt` are used to generate the definitions in the `include/mysqld_error.h` and `include/mysqld_ername.h` MySQL source files.
- The SQLSTATE values listed in `share/errmsg.txt` are used to generate the definitions in the `include/sql_state.h` MySQL source file.

Because updates are frequent, it is possible that these files contain additional error information not listed here.

- Error: `1000` SQLSTATE: `HY000` (`ER_HASHCHK`)

  Message: hashchk
- Error: `1001` SQLSTATE: `HY000` (`ER_NISAMCHK`)

  Message: isamchk
- Error: `1002` SQLSTATE: `HY000` (`ER_NO`)

  Message: NO
- Error: `1003` SQLSTATE: `HY000` (`ER_YES`)

  Message: YES
- Error: `1004` SQLSTATE: `HY000` (`ER_CANT_CREATE_FILE`)

  Message: Can't create file '%s' (errno: %d)
- Error: `1005` SQLSTATE: `HY000` (`ER_CANT_CREATE_TABLE`)

  Message: Can't create table '%s' (errno: %d)
- Error: `1006` SQLSTATE: `HY000` (`ER_CANT_CREATE_DB`)

  Message: Can't create database '%s' (errno: %d)
- Error: `1007` SQLSTATE: `HY000` (`ER_DB_CREATE_EXISTS`)

  Message: Can't create database '%s'; database exists
- Error: `1008` SQLSTATE: `HY000` (`ER_DB_DROP_EXISTS`)

Message: Can't drop database '%s'; database doesn't exist

- Error: 1009 SQLSTATE: HY000 (ER_DB_DROP_DELETE)

  Message: Error dropping database (can't delete '%s', errno: %d)

- Error: 1010 SQLSTATE: HY000 (ER_DB_DROP_RMDIR)

  Message: Error dropping database (can't rmdir '%s', errno: %d)

- Error: 1011 SQLSTATE: HY000 (ER_CANT_DELETE_FILE)

  Message: Error on delete of '%s' (errno: %d)

- Error: 1012 SQLSTATE: HY000 (ER_CANT_FIND_SYSTEM_REC)

  Message: Can't read record in system table

- Error: 1013 SQLSTATE: HY000 (ER_CANT_GET_STAT)

  Message: Can't get status of '%s' (errno: %d)

- Error: 1014 SQLSTATE: HY000 (ER_CANT_GET_WD)

  Message: Can't get working directory (errno: %d)

- Error: 1015 SQLSTATE: HY000 (ER_CANT_LOCK)

  Message: Can't lock file (errno: %d)

- Error: 1016 SQLSTATE: HY000 (ER_CANT_OPEN_FILE)

  Message: Can't open file: '%s' (errno: %d)

- Error: 1017 SQLSTATE: HY000 (ER_FILE_NOT_FOUND)

  Message: Can't find file: '%s' (errno: %d)

- Error: 1018 SQLSTATE: HY000 (ER_CANT_READ_DIR)

  Message: Can't read dir of '%s' (errno: %d)

- Error: 1019 SQLSTATE: HY000 (ER_CANT_SET_WD)

  Message: Can't change dir to '%s' (errno: %d)

- Error: 1020 SQLSTATE: HY000 (ER_CHECKREAD)

  Message: Record has changed since last read in table '%s'

- Error: 1021 SQLSTATE: HY000 (ER_DISK_FULL)

  Message: Disk full (%s); waiting for someone to free some space...

- Error: 1022 SQLSTATE: 23000 (ER_DUP_KEY)

  Message: Can't write; duplicate key in table '%s'

- Error: 1023 SQLSTATE: HY000 (ER_ERROR_ON_CLOSE)

  Message: Error on close of '%s' (errno: %d)

- Error: 1024 SQLSTATE: HY000 (ER_ERROR_ON_READ)

Message: Error reading file '%s' (errno: %d)

- Error: 1025 SQLSTATE: HY000 (ER_ERROR_ON_RENAME)

  Message: Error on rename of '%s' to '%s' (errno: %d)
- Error: 1026 SQLSTATE: HY000 (ER_ERROR_ON_WRITE)

  Message: Error writing file '%s' (errno: %d)
- Error: 1027 SQLSTATE: HY000 (ER_FILE_USED)

  Message: '%s' is locked against change
- Error: 1028 SQLSTATE: HY000 (ER_FILSORT_ABORT)

  Message: Sort aborted
- Error: 1029 SQLSTATE: HY000 (ER_FORM_NOT_FOUND)

  Message: View '%s' doesn't exist for '%s'
- Error: 1030 SQLSTATE: HY000 (ER_GET_ERRNO)

  Message: Got error %d from storage engine
- Error: 1031 SQLSTATE: HY000 (ER_ILLEGAL_HA)

  Message: Table storage engine for '%s' doesn't have this option
- Error: 1032 SQLSTATE: HY000 (ER_KEY_NOT_FOUND)

  Message: Can't find record in '%s'
- Error: 1033 SQLSTATE: HY000 (ER_NOT_FORM_FILE)

  Message: Incorrect information in file: '%s'
- Error: 1034 SQLSTATE: HY000 (ER_NOT_KEYFILE)

  Message: Incorrect key file for table '%s'; try to repair it
- Error: 1035 SQLSTATE: HY000 (ER_OLD_KEYFILE)

  Message: Old key file for table '%s'; repair it!
- Error: 1036 SQLSTATE: HY000 (ER_OPEN_AS_READONLY)

  Message: Table '%s' is read only
- Error: 1037 SQLSTATE: HY001 (ER_OUTOFMEMORY)

  Message: Out of memory; restart server and try again (needed %d bytes)
- Error: 1038 SQLSTATE: HY001 (ER_OUT_OF_SORTMEMORY)

  Message: Out of sort memory; increase server sort buffer size
- Error: 1039 SQLSTATE: HY000 (ER_UNEXPECTED_EOF)

  Message: Unexpected EOF found when reading file '%s' (errno: %d)
- Error: 1040 SQLSTATE: 08004 (ER_CON_COUNT_ERROR)

Message: Too many connections

- Error: 1041 SQLSTATE: HY000 (ER_OUT_OF_RESOURCES)

  Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- Error: 1042 SQLSTATE: 08S01 (ER_BAD_HOST_ERROR)

  Message: Can't get hostname for your address

- Error: 1043 SQLSTATE: 08S01 (ER_HANDSHAKE_ERROR)

  Message: Bad handshake

- Error: 1044 SQLSTATE: 42000 (ER_DBACCESS_DENIED_ERROR)

  Message: Access denied for user '%s'@'%s' to database '%s'

- Error: 1045 SQLSTATE: 28000 (ER_ACCESS_DENIED_ERROR)

  Message: Access denied for user '%s'@'%s' (using password: %s)

- Error: 1046 SQLSTATE: 3D000 (ER_NO_DB_ERROR)

  Message: No database selected

- Error: 1047 SQLSTATE: 08S01 (ER_UNKNOWN_COM_ERROR)

  Message: Unknown command

- Error: 1048 SQLSTATE: 23000 (ER_BAD_NULL_ERROR)

  Message: Column '%s' cannot be null

- Error: 1049 SQLSTATE: 42000 (ER_BAD_DB_ERROR)

  Message: Unknown database '%s'

- Error: 1050 SQLSTATE: 42S01 (ER_TABLE_EXISTS_ERROR)

  Message: Table '%s' already exists

- Error: 1051 SQLSTATE: 42S02 (ER_BAD_TABLE_ERROR)

  Message: Unknown table '%s'

- Error: 1052 SQLSTATE: 23000 (ER_NON_UNIQ_ERROR)

  Message: Column '%s' in %s is ambiguous

- Error: 1053 SQLSTATE: 08S01 (ER_SERVER_SHUTDOWN)

  Message: Server shutdown in progress

- Error: 1054 SQLSTATE: 42S22 (ER_BAD_FIELD_ERROR)

  Message: Unknown column '%s' in '%s'

- Error: 1055 SQLSTATE: 42000 (ER_WRONG_FIELD_WITH_GROUP)

  Message: '%s' isn't in GROUP BY

- Error: 1056 SQLSTATE: 42000 (ER_WRONG_GROUP_FIELD)

  Message: Can't group on '%s'
- Error: 1057 SQLSTATE: 42000 (ER_WRONG_SUM_SELECT)

  Message: Statement has sum functions and columns in same statement
- Error: 1058 SQLSTATE: 21S01 (ER_WRONG_VALUE_COUNT)

  Message: Column count doesn't match value count
- Error: 1059 SQLSTATE: 42000 (ER_TOO_LONG_IDENT)

  Message: Identifier name '%s' is too long
- Error: 1060 SQLSTATE: 42S21 (ER_DUP_FIELDNAME)

  Message: Duplicate column name '%s'
- Error: 1061 SQLSTATE: 42000 (ER_DUP_KEYNAME)

  Message: Duplicate key name '%s'
- Error: 1062 SQLSTATE: 23000 (ER_DUP_ENTRY)

  Message: Duplicate entry '%s' for key %d
- Error: 1063 SQLSTATE: 42000 (ER_WRONG_FIELD_SPEC)

  Message: Incorrect column specifier for column '%s'
- Error: 1064 SQLSTATE: 42000 (ER_PARSE_ERROR)

  Message: %s near '%s' at line %d
- Error: 1065 SQLSTATE: 42000 (ER_EMPTY_QUERY)

  Message: Query was empty
- Error: 1066 SQLSTATE: 42000 (ER_NONUNIQ_TABLE)

  Message: Not unique table/alias: '%s'
- Error: 1067 SQLSTATE: 42000 (ER_INVALID_DEFAULT)

  Message: Invalid default value for '%s'
- Error: 1068 SQLSTATE: 42000 (ER_MULTIPLE_PRI_KEY)

  Message: Multiple primary key defined
- Error: 1069 SQLSTATE: 42000 (ER_TOO_MANY_KEYS)

  Message: Too many keys specified; max %d keys allowed
- Error: 1070 SQLSTATE: 42000 (ER_TOO_MANY_KEY_PARTS)

  Message: Too many key parts specified; max %d parts allowed
- Error: 1071 SQLSTATE: 42000 (ER_TOO_LONG_KEY)

  Message: Specified key was too long; max key length is %d bytes
- Error: 1072 SQLSTATE: 42000 (ER_KEY_COLUMN_DOES_NOT_EXITS)

Message: Key column '%s' doesn't exist in table

- Error: 1073 SQLSTATE: 42000 (ER_BLOB_USED_AS_KEY)

  Message: BLOB column '%s' can't be used in key specification with the used table type

- Error: 1074 SQLSTATE: 42000 (ER_TOO_BIG_FIELDLENGTH)

  Message: Column length too big for column '%s' (max = %d); use BLOB or TEXT instead

- Error: 1075 SQLSTATE: 42000 (ER_WRONG_AUTO_KEY)

  Message: Incorrect table definition; there can be only one auto column and it must be defined as a key

- Error: 1076 SQLSTATE: HY000 (ER_READY)

  Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d

- Error: 1077 SQLSTATE: HY000 (ER_NORMAL_SHUTDOWN)

  Message: %s: Normal shutdown

- Error: 1078 SQLSTATE: HY000 (ER_GOT_SIGNAL)

  Message: %s: Got signal %d. Aborting!

- Error: 1079 SQLSTATE: HY000 (ER_SHUTDOWN_COMPLETE)

  Message: %s: Shutdown complete

- Error: 1080 SQLSTATE: 08S01 (ER_FORCING_CLOSE)

  Message: %s: Forcing close of thread %ld user: '%s'

- Error: 1081 SQLSTATE: 08S01 (ER_IPSOCK_ERROR)

  Message: Can't create IP socket

- Error: 1082 SQLSTATE: 42S12 (ER_NO_SUCH_INDEX)

  Message: Table '%s' has no index like the one used in CREATE INDEX; recreate the table

- Error: 1083 SQLSTATE: 42000 (ER_WRONG_FIELD_TERMINATORS)

  Message: Field separator argument is not what is expected; check the manual

- Error: 1084 SQLSTATE: 42000 (ER_BLOBS_AND_NO_TERMINATED)

  Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'

- Error: 1085 SQLSTATE: HY000 (ER_TEXTFILE_NOT_READABLE)

  Message: The file '%s' must be in the database directory or be readable by all

- Error: 1086 SQLSTATE: HY000 (ER_FILE_EXISTS_ERROR)

  Message: File '%s' already exists

- Error: 1087 SQLSTATE: HY000 (ER_LOAD_INFO)

  Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld

- Error: 1088 SQLSTATE: HY000 (ER_ALTER_INFO)

Message: Records: %ld Duplicates: %ld

- Error: 1089 SQLSTATE: HY000 (ER_WRONG_SUB_KEY)

  Message: Incorrect sub part key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique sub keys

- Error: 1090 SQLSTATE: 42000 (ER_CANT_REMOVE_ALL_FIELDS)

  Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead

- Error: 1091 SQLSTATE: 42000 (ER_CANT_DROP_FIELD_OR_KEY)

  Message: Can't DROP '%s'; check that column/key exists

- Error: 1092 SQLSTATE: HY000 (ER_INSERT_INFO)

  Message: Records: %ld Duplicates: %ld Warnings: %ld

- Error: 1093 SQLSTATE: HY000 (ER_UPDATE_TABLE_USED)

  Message: You can't specify target table '%s' for update in FROM clause

- Error: 1094 SQLSTATE: HY000 (ER_NO_SUCH_THREAD)

  Message: Unknown thread id: %lu

- Error: 1095 SQLSTATE: HY000 (ER_KILL_DENIED_ERROR)

  Message: You are not owner of thread %lu

- Error: 1096 SQLSTATE: HY000 (ER_NO_TABLES_USED)

  Message: No tables used

- Error: 1097 SQLSTATE: HY000 (ER_TOO_BIG_SET)

  Message: Too many strings for column %s and SET

- Error: 1098 SQLSTATE: HY000 (ER_NO_UNIQUE_LOGFILE)

  Message: Can't generate a unique log-filename %s.(1-999)

- Error: 1099 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED_FOR_WRITE)

  Message: Table '%s' was locked with a READ lock and can't be updated

- Error: 1100 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED)

  Message: Table '%s' was not locked with LOCK TABLES

- Error: 1101 SQLSTATE: 42000 (ER_BLOB_CANT_HAVE_DEFAULT)

  Message: BLOB/TEXT column '%s' can't have a default value

- Error: 1102 SQLSTATE: 42000 (ER_WRONG_DB_NAME)

  Message: Incorrect database name '%s'

- Error: 1103 SQLSTATE: 42000 (ER_WRONG_TABLE_NAME)

  Message: Incorrect table name '%s'

- Error: 1104 SQLSTATE: 42000 (ER_TOO_BIG_SELECT)

Message: The SELECT would examine more than MAX_JOIN_SIZE rows; check your WHERE and use SET SQL_BIG_SELECTS=1 or SET SQL_MAX_JOIN_SIZE=# if the SELECT is okay

- Error: 1105 SQLSTATE: HY000 (ER_UNKNOWN_ERROR)

  Message: Unknown error

- Error: 1106 SQLSTATE: 42000 (ER_UNKNOWN_PROCEDURE)

  Message: Unknown procedure '%s'

- Error: 1107 SQLSTATE: 42000 (ER_WRONG_PARAMCOUNT_TO_PROCEDURE)

  Message: Incorrect parameter count to procedure '%s'

- Error: 1108 SQLSTATE: HY000 (ER_WRONG_PARAMETERS_TO_PROCEDURE)

  Message: Incorrect parameters to procedure '%s'

- Error: 1109 SQLSTATE: 42S02 (ER_UNKNOWN_TABLE)

  Message: Unknown table '%s' in %s

- Error: 1110 SQLSTATE: 42000 (ER_FIELD_SPECIFIED_TWICE)

  Message: Column '%s' specified twice

- Error: 1111 SQLSTATE: HY000 (ER_INVALID_GROUP_FUNC_USE)

  Message: Invalid use of group function

- Error: 1112 SQLSTATE: 42000 (ER_UNSUPPORTED_EXTENSION)

  Message: Table '%s' uses an extension that doesn't exist in this MySQL version

- Error: 1113 SQLSTATE: 42000 (ER_TABLE_MUST_HAVE_COLUMNS)

  Message: A table must have at least 1 column

- Error: 1114 SQLSTATE: HY000 (ER_RECORD_FILE_FULL)

  Message: The table '%s' is full

- Error: 1115 SQLSTATE: 42000 (ER_UNKNOWN_CHARACTER_SET)

  Message: Unknown character set: '%s'

- Error: 1116 SQLSTATE: HY000 (ER_TOO_MANY_TABLES)

  Message: Too many tables; MySQL can only use %d tables in a join

- Error: 1117 SQLSTATE: HY000 (ER_TOO_MANY_FIELDS)

  Message: Too many columns

- Error: 1118 SQLSTATE: 42000 (ER_TOO_BIG_ROWSIZE)

  Message: Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. You have to change some columns to TEXT or BLOBs

- Error: 1119 SQLSTATE: HY000 (ER_STACK_OVERRUN)

  Message: Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld -O thread_stack=#' to

specify a bigger stack if needed

- Error: 1120 SQLSTATE: 42000 (ER_WRONG_OUTER_JOIN)

  Message: Cross dependency found in OUTER JOIN; examine your ON conditions

- Error: 1121 SQLSTATE: 42000 (ER_NULL_COLUMN_IN_INDEX)

  Message: Column '%s' is used with UNIQUE or INDEX but is not defined as NOT NULL

- Error: 1122 SQLSTATE: HY000 (ER_CANT_FIND_UDF)

  Message: Can't load function '%s'

- Error: 1123 SQLSTATE: HY000 (ER_CANT_INITIALIZE_UDF)

  Message: Can't initialize function '%s'; %s

- Error: 1124 SQLSTATE: HY000 (ER_UDF_NO_PATHS)

  Message: No paths allowed for shared library

- Error: 1125 SQLSTATE: HY000 (ER_UDF_EXISTS)

  Message: Function '%s' already exists

- Error: 1126 SQLSTATE: HY000 (ER_CANT_OPEN_LIBRARY)

  Message: Can't open shared library '%s' (errno: %d %s)

- Error: 1127 SQLSTATE: HY000 (ER_CANT_FIND_DL_ENTRY)

  Message: Can't find symbol '%s' in library

- Error: 1128 SQLSTATE: HY000 (ER_FUNCTION_NOT_DEFINED)

  Message: Function '%s' is not defined

- Error: 1129 SQLSTATE: HY000 (ER_HOST_IS_BLOCKED)

  Message: Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'

- Error: 1130 SQLSTATE: HY000 (ER_HOST_NOT_PRIVILEGED)

  Message: Host '%s' is not allowed to connect to this MySQL server

- Error: 1131 SQLSTATE: 42000 (ER_PASSWORD_ANONYMOUS_USER)

  Message: You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords

- Error: 1132 SQLSTATE: 42000 (ER_PASSWORD_NOT_ALLOWED)

  Message: You must have privileges to update tables in the mysql database to be able to change passwords for others

- Error: 1133 SQLSTATE: 42000 (ER_PASSWORD_NO_MATCH)

  Message: Can't find any matching row in the user table

- Error: 1134 SQLSTATE: HY000 (ER_UPDATE_INFO)

  Message: Rows matched: %ld Changed: %ld Warnings: %ld

- Error: 1135 SQLSTATE: HY000 (ER_CANT_CREATE_THREAD)

  Message: Can't create a new thread (errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug

- Error: 1136 SQLSTATE: 21S01 (ER_WRONG_VALUE_COUNT_ON_ROW)

  Message: Column count doesn't match value count at row %ld

- Error: 1137 SQLSTATE: HY000 (ER_CANT_REOPEN_TABLE)

  Message: Can't reopen table: '%s'

- Error: 1138 SQLSTATE: 22004 (ER_INVALID_USE_OF_NULL)

  Message: Invalid use of NULL value

- Error: 1139 SQLSTATE: 42000 (ER_REGEXP_ERROR)

  Message: Got error '%s' from regexp

- Error: 1140 SQLSTATE: 42000 (ER_MIX_OF_GROUP_FUNC_AND_FIELDS)

  Message: Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause

- Error: 1141 SQLSTATE: 42000 (ER_NONEXISTING_GRANT)

  Message: There is no such grant defined for user '%s' on host '%s'

- Error: 1142 SQLSTATE: 42000 (ER_TABLEACCESS_DENIED_ERROR)

  Message: %s command denied to user '%s'@'%s' for table '%s'

- Error: 1143 SQLSTATE: 42000 (ER_COLUMNACCESS_DENIED_ERROR)

  Message: %s command denied to user '%s'@'%s' for column '%s' in table '%s'

- Error: 1144 SQLSTATE: 42000 (ER_ILLEGAL_GRANT_FOR_TABLE)

  Message: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used

- Error: 1145 SQLSTATE: 42000 (ER_GRANT_WRONG_HOST_OR_USER)

  Message: The host or user argument to GRANT is too long

- Error: 1146 SQLSTATE: 42S02 (ER_NO_SUCH_TABLE)

  Message: Table '%s.%s' doesn't exist

- Error: 1147 SQLSTATE: 42000 (ER_NONEXISTING_TABLE_GRANT)

  Message: There is no such grant defined for user '%s' on host '%s' on table '%s'

- Error: 1148 SQLSTATE: 42000 (ER_NOT_ALLOWED_COMMAND)

  Message: The used command is not allowed with this MySQL version

- Error: 1149 SQLSTATE: 42000 (ER_SYNTAX_ERROR)

  Message: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use

- Error: 1150 SQLSTATE: HY000 (ER_DELAYED_CANT_CHANGE_LOCK)

Message: Delayed insert thread couldn't get requested lock for table %s

- Error: 1151 SQLSTATE: HY000 (ER_TOO_MANY_DELAYED_THREADS)

  Message: Too many delayed threads in use

- Error: 1152 SQLSTATE: 08S01 (ER_ABORTING_CONNECTION)

  Message: Aborted connection %ld to db: '%s' user: '%s' (%s)

- Error: 1153 SQLSTATE: 08S01 (ER_NET_PACKET_TOO_LARGE)

  Message: Got a packet bigger than 'max_allowed_packet' bytes

- Error: 1154 SQLSTATE: 08S01 (ER_NET_READ_ERROR_FROM_PIPE)

  Message: Got a read error from the connection pipe

- Error: 1155 SQLSTATE: 08S01 (ER_NET_FCNTL_ERROR)

  Message: Got an error from fcntl()

- Error: 1156 SQLSTATE: 08S01 (ER_NET_PACKETS_OUT_OF_ORDER)

  Message: Got packets out of order

- Error: 1157 SQLSTATE: 08S01 (ER_NET_UNCOMPRESS_ERROR)

  Message: Couldn't uncompress communication packet

- Error: 1158 SQLSTATE: 08S01 (ER_NET_READ_ERROR)

  Message: Got an error reading communication packets

- Error: 1159 SQLSTATE: 08S01 (ER_NET_READ_INTERRUPTED)

  Message: Got timeout reading communication packets

- Error: 1160 SQLSTATE: 08S01 (ER_NET_ERROR_ON_WRITE)

  Message: Got an error writing communication packets

- Error: 1161 SQLSTATE: 08S01 (ER_NET_WRITE_INTERRUPTED)

  Message: Got timeout writing communication packets

- Error: 1162 SQLSTATE: 42000 (ER_TOO_LONG_STRING)

  Message: Result string is longer than 'max_allowed_packet' bytes

- Error: 1163 SQLSTATE: 42000 (ER_TABLE_CANT_HANDLE_BLOB)

  Message: The used table type doesn't support BLOB/TEXT columns

- Error: 1164 SQLSTATE: 42000 (ER_TABLE_CANT_HANDLE_AUTO_INCREMENT)

  Message: The used table type doesn't support AUTO_INCREMENT columns

- Error: 1165 SQLSTATE: HY000 (ER_DELAYED_INSERT_TABLE_LOCKED)

  Message: INSERT DELAYED can't be used with table '%s' because it is locked with LOCK TABLES

- Error: 1166 SQLSTATE: 42000 (ER_WRONG_COLUMN_NAME)

Message: Incorrect column name '%s'

- Error: 1167 SQLSTATE: 42000 (ER_WRONG_KEY_COLUMN)

  Message: The used storage engine can't index column '%s'

- Error: 1168 SQLSTATE: HY000 (ER_WRONG_MRG_TABLE)

  Message: All tables in the MERGE table are not identically defined

- Error: 1169 SQLSTATE: 23000 (ER_DUP_UNIQUE)

  Message: Can't write, because of unique constraint, to table '%s'

- Error: 1170 SQLSTATE: 42000 (ER_BLOB_KEY_WITHOUT_LENGTH)

  Message: BLOB/TEXT column '%s' used in key specification without a key length

- Error: 1171 SQLSTATE: 42000 (ER_PRIMARY_CANT_HAVE_NULL)

  Message: All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead

- Error: 1172 SQLSTATE: 42000 (ER_TOO_MANY_ROWS)

  Message: Result consisted of more than one row

- Error: 1173 SQLSTATE: 42000 (ER_REQUIRES_PRIMARY_KEY)

  Message: This table type requires a primary key

- Error: 1174 SQLSTATE: HY000 (ER_NO_RAID_COMPILED)

  Message: This version of MySQL is not compiled with RAID support

- Error: 1175 SQLSTATE: HY000 (ER_UPDATE_WITHOUT_KEY_IN_SAFE_MODE)

  Message: You are using safe update mode and you tried to update a table without a WHERE that uses a KEY column

- Error: 1176 SQLSTATE: HY000 (ER_KEY_DOES_NOT_EXITS)

  Message: Key '%s' doesn't exist in table '%s'

- Error: 1177 SQLSTATE: 42000 (ER_CHECK_NO_SUCH_TABLE)

  Message: Can't open table

- Error: 1178 SQLSTATE: 42000 (ER_CHECK_NOT_IMPLEMENTED)

  Message: The storage engine for the table doesn't support %s

- Error: 1179 SQLSTATE: 25000 (ER_CANT_DO_THIS_DURING_AN_TRANSACTION)

  Message: You are not allowed to execute this command in a transaction

- Error: 1180 SQLSTATE: HY000 (ER_ERROR_DURING_COMMIT)

  Message: Got error %d during COMMIT

- Error: 1181 SQLSTATE: HY000 (ER_ERROR_DURING_ROLLBACK)

  Message: Got error %d during ROLLBACK

- Error: 1182 SQLSTATE: HY000 (ER_ERROR_DURING_FLUSH_LOGS)

  Message: Got error %d during FLUSH_LOGS

- Error: 1183 SQLSTATE: HY000 (ER_ERROR_DURING_CHECKPOINT)

  Message: Got error %d during CHECKPOINT

- Error: 1184 SQLSTATE: 08S01 (ER_NEW_ABORTING_CONNECTION)

  Message: Aborted connection %ld to db: '%s' user: '%s' host: '%s' (%s)

- Error: 1185 SQLSTATE: HY000 (ER_DUMP_NOT_IMPLEMENTED)

  Message: The storage engine for the table does not support binary table dump

- Error: 1186 SQLSTATE: HY000 (ER_FLUSH_MASTER_BINLOG_CLOSED)

  Message: Binlog closed, cannot RESET MASTER

- Error: 1187 SQLSTATE: HY000 (ER_INDEX_REBUILD)

  Message: Failed rebuilding the index of dumped table '%s'

- Error: 1188 SQLSTATE: HY000 (ER_MASTER)

  Message: Error from master: '%s'

- Error: 1189 SQLSTATE: 08S01 (ER_MASTER_NET_READ)

  Message: Net error reading from master

- Error: 1190 SQLSTATE: 08S01 (ER_MASTER_NET_WRITE)

  Message: Net error writing to master

- Error: 1191 SQLSTATE: HY000 (ER_FT_MATCHING_KEY_NOT_FOUND)

  Message: Can't find FULLTEXT index matching the column list

- Error: 1192 SQLSTATE: HY000 (ER_LOCK_OR_ACTIVE_TRANSACTION)

  Message: Can't execute the given command because you have active locked tables or an active transaction

- Error: 1193 SQLSTATE: HY000 (ER_UNKNOWN_SYSTEM_VARIABLE)

  Message: Unknown system variable '%s'

- Error: 1194 SQLSTATE: HY000 (ER_CRASHED_ON_USAGE)

  Message: Table '%s' is marked as crashed and should be repaired

- Error: 1195 SQLSTATE: HY000 (ER_CRASHED_ON_REPAIR)

  Message: Table '%s' is marked as crashed and last (automatic?) repair failed

- Error: 1196 SQLSTATE: HY000 (ER_WARNING_NOT_COMPLETE_ROLLBACK)

  Message: Some non-transactional changed tables couldn't be rolled back

- Error: 1197 SQLSTATE: HY000 (ER_TRANS_CACHE_FULL)

  Message: Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage; increase this mysqld variable and try again

- Error: 1198 SQLSTATE: HY000 (ER_SLAVE_MUST_STOP)

  Message: This operation cannot be performed with a running slave; run STOP SLAVE first

- Error: 1199 SQLSTATE: HY000 (ER_SLAVE_NOT_RUNNING)

  Message: This operation requires a running slave; configure slave and do START SLAVE

- Error: 1200 SQLSTATE: HY000 (ER_BAD_SLAVE)

  Message: The server is not configured as slave; fix in config file or with CHANGE MASTER TO

- Error: 1201 SQLSTATE: HY000 (ER_MASTER_INFO)

  Message: Could not initialize master info structure; more error messages can be found in the MySQL error log

- Error: 1202 SQLSTATE: HY000 (ER_SLAVE_THREAD)

  Message: Could not create slave thread; check system resources

- Error: 1203 SQLSTATE: 42000 (ER_TOO_MANY_USER_CONNECTIONS)

  Message: User %s already has more than 'max_user_connections' active connections

- Error: 1204 SQLSTATE: HY000 (ER_SET_CONSTANTS_ONLY)

  Message: You may only use constant expressions with SET

- Error: 1205 SQLSTATE: HY000 (ER_LOCK_WAIT_TIMEOUT)

  Message: Lock wait timeout exceeded; try restarting transaction

- Error: 1206 SQLSTATE: HY000 (ER_LOCK_TABLE_FULL)

  Message: The total number of locks exceeds the lock table size

- Error: 1207 SQLSTATE: 25000 (ER_READ_ONLY_TRANSACTION)

  Message: Update locks cannot be acquired during a READ UNCOMMITTED transaction

- Error: 1208 SQLSTATE: HY000 (ER_DROP_DB_WITH_READ_LOCK)

  Message: DROP DATABASE not allowed while thread is holding global read lock

- Error: 1209 SQLSTATE: HY000 (ER_CREATE_DB_WITH_READ_LOCK)

  Message: CREATE DATABASE not allowed while thread is holding global read lock

- Error: 1210 SQLSTATE: HY000 (ER_WRONG_ARGUMENTS)

  Message: Incorrect arguments to %s

- Error: 1211 SQLSTATE: 42000 (ER_NO_PERMISSION_TO_CREATE_USER)

  Message: '%s'@'%s' is not allowed to create new users

- Error: 1212 SQLSTATE: HY000 (ER_UNION_TABLES_IN_DIFFERENT_DIR)

  Message: Incorrect table definition; all MERGE tables must be in the same database

- Error: 1213 SQLSTATE: 40001 (ER_LOCK_DEADLOCK)

  Message: Deadlock found when trying to get lock; try restarting transaction

- Error: 1214 SQLSTATE: HY000 (ER_TABLE_CANT_HANDLE_FT)

  Message: The used table type doesn't support FULLTEXT indexes
- Error: 1215 SQLSTATE: HY000 (ER_CANNOT_ADD_FOREIGN)

  Message: Cannot add foreign key constraint
- Error: 1216 SQLSTATE: 23000 (ER_NO_REFERENCED_ROW)

  Message: Cannot add or update a child row: a foreign key constraint fails
- Error: 1217 SQLSTATE: 23000 (ER_ROW_IS_REFERENCED)

  Message: Cannot delete or update a parent row: a foreign key constraint fails
- Error: 1218 SQLSTATE: 08S01 (ER_CONNECT_TO_MASTER)

  Message: Error connecting to master: %s
- Error: 1219 SQLSTATE: HY000 (ER_QUERY_ON_MASTER)

  Message: Error running query on master: %s
- Error: 1220 SQLSTATE: HY000 (ER_ERROR_WHEN_EXECUTING_COMMAND)

  Message: Error when executing command %s: %s
- Error: 1221 SQLSTATE: HY000 (ER_WRONG_USAGE)

  Message: Incorrect usage of %s and %s
- Error: 1222 SQLSTATE: 21000 (ER_WRONG_NUMBER_OF_COLUMNS_IN_SELECT)

  Message: The used SELECT statements have a different number of columns

- Error: 1251 SQLSTATE: 08004 (ER_NOT_SUPPORTED_AUTH_MODE)

  Message: Client does not support authentication protocol requested by server; consider upgrading MySQL client

- Error: 1252 SQLSTATE: 42000 (ER_SPATIAL_CANT_HAVE_NULL)

  Message: All parts of a SPATIAL index must be NOT NULL

- Error: 1253 SQLSTATE: 42000 (ER_COLLATION_CHARSET_MISMATCH)

  Message: COLLATION '%s' is not valid for CHARACTER SET '%s'

- Error: 1254 SQLSTATE: HY000 (ER_SLAVE_WAS_RUNNING)

  Message: Slave is already running

- Error: 1255 SQLSTATE: HY000 (ER_SLAVE_WAS_NOT_RUNNING)

  Message: Slave already has been stopped

- Error: 1256 SQLSTATE: HY000 (ER_TOO_BIG_FOR_UNCOMPRESS)

  Message: Uncompressed data size too large; the maximum size is %d (probably, length of uncompressed data was corrupted)

- Error: 1257 SQLSTATE: HY000 (ER_ZLIB_Z_MEM_ERROR)

  Message: ZLIB: Not enough memory

- Error: 1258 SQLSTATE: HY000 (ER_ZLIB_Z_BUF_ERROR)

  Message: ZLIB: Not enough room in the output buffer (probably, length of uncompressed data was corrupted)

- Error: 1259 SQLSTATE: HY000 (ER_ZLIB_Z_DATA_ERROR)

  Message: ZLIB: Input data corrupted

- Error: 1260 SQLSTATE: HY000 (ER_CUT_VALUE_GROUP_CONCAT)

  Message: %d line(s) were cut by GROUP_CONCAT()

- Error: 1261 SQLSTATE: 01000 (ER_WARN_TOO_FEW_RECORDS)

  Message: Row %ld doesn't contain data for all columns

- Error: 1262 SQLSTATE: 01000 (ER_WARN_TOO_MANY_RECORDS)

  Message: Row %ld was truncated; it contained more data than there were input columns

- Error: 1263 SQLSTATE: 22004 (ER_WARN_NULL_TO_NOTNULL)

  Message: Column set to default value; NULL supplied to NOT NULL column '%s' at row %ld

- Error: 1264 SQLSTATE: 22003 (ER_WARN_DATA_OUT_OF_RANGE)

  Message: Out of range value for column '%s' at row %ld

- Error: 1265 SQLSTATE: 01000 (WARN_DATA_TRUNCATED)

  Message: Data truncated for column '%s' at row %ld

- Error: 1266 SQLSTATE: HY000 (ER_WARN_USING_OTHER_HANDLER)

  Message: Using storage engine %s for table '%s'

- Error: 1267 SQLSTATE: HY000 (ER_CANT_AGGREGATE_2COLLATIONS)

  Message: Illegal mix of collations (%s,%s) and (%s,%s) for operation '%s'

- Error: 1268 SQLSTATE: HY000 (ER_DROP_USER)

  Message: Cannot drop one or more of the requested users

- Error: 1269 SQLSTATE: HY000 (ER_REVOKE_GRANTS)

  Message: Can't revoke all privileges for one or more of the requested users

- Error: 1270 SQLSTATE: HY000 (ER_CANT_AGGREGATE_3COLLATIONS)

  Message: Illegal mix of collations (%s,%s), (%s,%s), (%s,%s) for operation '%s'

- Error: 1271 SQLSTATE: HY000 (ER_CANT_AGGREGATE_NCOLLATIONS)

  Message: Illegal mix of collations for operation '%s'

- Error: 1272 SQLSTATE: HY000 (ER_VARIABLE_IS_NOT_STRUCT)

  Message: Variable '%s' is not a variable component (can't be used as XXXX.variable_name)

- Error: 1273 SQLSTATE: HY000 (ER_UNKNOWN_COLLATION)

  Message: Unknown collation: '%s'

- Error: 1274 SQLSTATE: HY000 (ER_SLAVE_IGNORED_SSL_PARAMS)

  Message: SSL parameters in CHANGE MASTER are ignored because this MySQL slave was compiled without SSL support; they can be used later if MySQL slave with SSL is started

- Error: 1275 SQLSTATE: HY000 (ER_SERVER_IS_IN_SECURE_AUTH_MODE)

  Message: Server is running in --secure-auth mode, but '%s'@'%s' has a password in the old format; please change the password to the new format

- Error: 1276 SQLSTATE: HY000 (ER_WARN_FIELD_RESOLVED)

  Message: Field or reference '%s%s%s%s%s' of SELECT #%d was resolved in SELECT #%d

- Error: 1277 SQLSTATE: HY000 (ER_BAD_SLAVE_UNTIL_COND)

  Message: Incorrect parameter or combination of parameters for START SLAVE UNTIL

- Error: 1278 SQLSTATE: HY000 (ER_MISSING_SKIP_SLAVE)

  Message: It is recommended to use --skip-slave-start when doing step-by-step replication with START SLAVE UNTIL; otherwise, you will get problems if you get an unexpected slave's mysqld restart

- Error: 1279 SQLSTATE: HY000 (ER_UNTIL_COND_IGNORED)

  Message: SQL thread is not to be started so UNTIL options are ignored

- Error: 1280 SQLSTATE: 42000 (ER_WRONG_NAME_FOR_INDEX)

  Message: Incorrect index name '%s'

- Error: 1281 SQLSTATE: 42000 (ER_WRONG_NAME_FOR_CATALOG)

  Message: Incorrect catalog name '%s'

- Error: 1282 SQLSTATE: HY000 (ER_WARN_QC_RESIZE)

  Message: Query cache failed to set size %lu; new query cache size is %lu

- Error: 1283 SQLSTATE: HY000 (ER_BAD_FT_COLUMN)

  Message: Column '%s' cannot be part of FULLTEXT index

- Error: 1284 SQLSTATE: HY000 (ER_UNKNOWN_KEY_CACHE)

  Message: Unknown key cache '%s'

- Error: 1285 SQLSTATE: HY000 (ER_WARN_HOSTNAME_WONT_WORK)

  Message: MySQL is started in --skip-name-resolve mode; you must restart it without this switch for this grant to work

- Error: 1286 SQLSTATE: 42000 (ER_UNKNOWN_STORAGE_ENGINE)

  Message: Unknown table engine '%s'

- Error: 1287 SQLSTATE: HY000 (ER_WARN_DEPRECATED_SYNTAX)

  Message: '%s' is deprecated; use '%s' instead

- Error: 1288 SQLSTATE: HY000 (ER_NON_UPDATABLE_TABLE)

  Message: The target table %s of the %s is not updatable

- Error: 1289 SQLSTATE: HY000 (ER_FEATURE_DISABLED)

  Message: The '%s' feature is disabled; you need MySQL built with '%s' to have it working

- Error: 1290 SQLSTATE: HY000 (ER_OPTION_PREVENTS_STATEMENT)

  Message: The MySQL server is running with the %s option so it cannot execute this statement

- Error: 1291 SQLSTATE: HY000 (ER_DUPLICATED_VALUE_IN_TYPE)

  Message: Column '%s' has duplicated value '%s' in %s

- Error: 1292 SQLSTATE: 22007 (ER_TRUNCATED_WRONG_VALUE)

  Message: Truncated incorrect %s value: '%s'

- Error: 1293 SQLSTATE: HY000 (ER_TOO_MUCH_AUTO_TIMESTAMP_COLS)

Message: Incorrect table definition; there can be only one TIMESTAMP column with CURRENT_TIMESTAMP in DEFAULT or ON UPDATE clause

- Error: 1294 SQLSTATE: HY000 (ER_INVALID_ON_UPDATE)

  Message: Invalid ON UPDATE clause for '%s' column

- Error: 1295 SQLSTATE: HY000 (ER_UNSUPPORTED_PS)

  Message: This command is not supported in the prepared statement protocol yet

- Error: 1296 SQLSTATE: HY000 (ER_GET_ERRMSG)

  Message: Got error %d '%s' from %s

- Error: 1297 SQLSTATE: HY000 (ER_GET_TEMPORARY_ERRMSG)

  Message: Got temporary error %d '%s' from %s

- Error: 1298 SQLSTATE: HY000 (ER_UNKNOWN_TIME_ZONE)

  Message: Unknown or incorrect time zone: '%s'

- Error: 1299 SQLSTATE: HY000 (ER_WARN_INVALID_TIMESTAMP)

  Message: Invalid TIMESTAMP value in column '%s' at row %ld

- Error: 1300 SQLSTATE: HY000 (ER_INVALID_CHARACTER_STRING)

  Message: Invalid %s character string: '%s'

- Error: 1301 SQLSTATE: HY000 (ER_WARN_ALLOWED_PACKET_OVERFLOWED)

  Message: Result of %s() was larger than max_allowed_packet (%ld) - truncated

- Error: 1302 SQLSTATE: HY000 (ER_CONFLICTING_DECLARATIONS)

- Error: 1405 SQLSTATE: HY000 (ER_PROC_AUTO_REVOKE_FAIL)

  Message: Failed to revoke all privileges to dropped routine

- Error: 1406 SQLSTATE: 22001 (ER_DATA_TOO_LONG)

  Message: Data too long for column '%s' at row %ld

- Error: 1407 SQLSTATE: 42000 (ER_SP_BAD_SQLSTATE)

  Message: Bad SQLSTATE: '%s'

- Error: 1408 SQLSTATE: HY000 (ER_STARTUP)

  Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d %s

- Error: 1409 SQLSTATE: HY000 (ER_LOAD_FROM_FIXED_SIZE_ROWS_TO_VAR)

  Message: Can't load value from file with fixed size rows to variable

- Error: 1410 SQLSTATE: 42000 (ER_CANT_CREATE_USER_WITH_GRANT)

  Message: You are not allowed to create a user with GRANT

- Error: 1411 SQLSTATE: HY000 (ER_WRONG_VALUE_FOR_TYPE)

  Message: Incorrect %s value: '%s' for function %s

- Error: 1412 SQLSTATE: HY000 (ER_TABLE_DEF_CHANGED)

  Message: Table definition has changed, please retry transaction

- Error: 1413 SQLSTATE: 42000 (ER_SP_DUP_HANDLER)

  Message: Duplicate handler declared in the same block

- Error: 1414 SQLSTATE: 42000 (ER_SP_NOT_VAR_ARG)

  Message: OUT or INOUT argument %d for routine %s is not a variable

- Error: 1415 SQLSTATE: 0A000 (ER_SP_NO_RETSET)

  Message: Not allowed to return a result set from a %s

- Error: 1416 SQLSTATE: 22003 (ER_CANT_CREATE_GEOMETRY_OBJECT)

  Message: Cannot get geometry object from data you send to the GEOMETRY field

- Error: 1417 SQLSTATE: HY000 (ER_FAILED_ROUTINE_BREAK_BINLOG)

  Message: A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes

- Error: 1418 SQLSTATE: HY000 (ER_BINLOG_UNSAFE_ROUTINE)

  Message: This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)

- Error: 1419 SQLSTATE: HY000 (ER_BINLOG_CREATE_ROUTINE_NEED_SUPER)

  Message: You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)

- Error: 1420 SQLSTATE: HY000 (ER_EXEC_STMT_WITH_OPEN_CURSOR)

  Message: You can't execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.

- Error: 1421 SQLSTATE: HY000 (ER_STMT_HAS_NO_OPEN_CURSOR)

  Message: The statement (%lu) has no open cursor.

- Error: 1422 SQLSTATE: HY000 (ER_COMMIT_NOT_ALLOWED_IN_SF_OR_TRG)

  Message: Explicit or implicit commit is not allowed in stored function or trigger.

- Error: 1423 SQLSTATE: HY000 (ER_NO_DEFAULT_FOR_VIEW_FIELD)

  Message: Field of view '%s.%s' underlying table doesn't have a default value

- Error: 1424 SQLSTATE: HY000 (ER_SP_NO_RECURSION)

  Message: Recursive stored functions and triggers are not allowed.

- Error: 1425 SQLSTATE: 42000 (ER_TOO_BIG_SCALE)

  Message: Too big scale %d specified for column '%s'. Maximum is %d.

- Error: 1426 SQLSTATE: 42000 (ER_TOO_BIG_PRECISION)

  Message: Too big precision %d specified for column '%s'. Maximum is %d.

- Error: 1427 SQLSTATE: 42000 (ER_M_BIGGER_THAN_D)

  Message: For float(M,D), double(M,D) or decimal(M,D), M must be >= D (column '%s').

- Error: 1428 SQLSTATE: HY000 (ER_WRONG_LOCK_OF_SYSTEM_TABLE)

  Message: You can't combine write-locking of system '%s.%s' table with other tables

- Error: 1429 SQLSTATE: HY000 (ER_CONNECT_TO_FOREIGN_DATA_SOURCE)

  Message: Unable to connect to foreign data source: %s

- Error: 1430 SQLSTATE: HY000 (ER_QUERY_ON_FOREIGN_DATA_SOURCE)

  Message: There was a problem processing the query on the foreign data source. Data source error: %-.64

- Error: 1431 SQLSTATE: HY000 (ER_FOREIGN_DATA_SOURCE_DOESNT_EXIST)

  Message: The foreign data source you are trying to reference does not exist. Data source error: %s

- Error: 1432 SQLSTATE: HY000 (ER_FOREIGN_DATA_STRING_INVALID_CANT_CREATE)

  Message: Can't create federated table. The data source connection string '%s' is not in the correct format

- Error: 1433 SQLSTATE: HY000 (ER_FOREIGN_DATA_STRING_INVALID)

  Message: The data source connection string '%s' is not in the correct format

- Error: 1434 SQLSTATE: HY000 (ER_CANT_CREATE_FEDERATED_TABLE)

  Message: Can't create federated table. Foreign data src error: %s

- Error: 1435 SQLSTATE: HY000 (ER_TRG_IN_WRONG_SCHEMA)

  Message: Trigger in wrong schema

- Error: 1436 SQLSTATE: HY000 (ER_STACK_OVERRUN_NEED_MORE)

  Message: Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld -O thread_stack=#' to specify a bigger stack.

- Error: 1437 SQLSTATE: 42000 (ER_TOO_LONG_BODY)

  Message: Routine body for '%s' is too long

- Error: 1438 SQLSTATE: HY000 (ER_WARN_CANT_DROP_DEFAULT_KEYCACHE)

  Message: Cannot drop default keycache

- Error: 1439 SQLSTATE: 42000 (ER_TOO_BIG_DISPLAYWIDTH)

  Message: Display width out of range for column '%s' (max = %d)

- Error: 1440 SQLSTATE: XAE08 (ER_XAER_DUPID)

  Message: XAER_DUPID: The XID already exists

- Error: 1441 SQLSTATE: 22008 (ER_DATETIME_FUNCTION_OVERFLOW)

  Message: Datetime function: %s field overflow

- Error: 1442 SQLSTATE: HY000 (ER_CANT_UPDATE_USED_TABLE_IN_SF_OR_TRG)

  Message: Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.

- Error: 1443 SQLSTATE: HY000 (ER_VIEW_PREVENT_UPDATE)

  Message: The definition of table '%s' prevents operation %s on table '%s'.

- Error: 1444 SQLSTATE: HY000 (ER_PS_NO_RECURSION)

  Message: The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner

- Error: 1445 SQLSTATE: HY000 (ER_SP_CANT_SET_AUTOCOMMIT)

  Message: Not allowed to set autocommit from a stored function or trigger

- Error: 1446 SQLSTATE: HY000 (ER_MALFORMED_DEFINER)

  Message: Definer is not fully qualified

- Error: 1447 SQLSTATE: HY000 (ER_VIEW_FRM_NO_USER)

  Message: View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!

- Error: 1448 SQLSTATE: HY000 (ER_VIEW_OTHER_USER)

  Message: You need the SUPER privilege for creation view with '%s'@'%s' definer

- Error: 1449 SQLSTATE: HY000 (ER_NO_SUCH_USER)

  Message: There is no '%s'@'%s' registered

- Error: 1450 SQLSTATE: HY000 (ER_FORBID_SCHEMA_CHANGE)

Message: Changing schema from '%s' to '%s' is not allowed.

- Error: 1451 SQLSTATE: 23000 (ER_ROW_IS_REFERENCED_2)

  Message: Cannot delete or update a parent row: a foreign key constraint fails (%s)

- Error: 1452 SQLSTATE: 23000 (ER_NO_REFERENCED_ROW_2)

  Message: Cannot add or update a child row: a foreign key constraint fails (%s)

- Error: 1453 SQLSTATE: 42000 (ER_SP_BAD_VAR_SHADOW)

  Message: Variable '%s' must be quoted with `...`, or renamed

- Error: 1454 SQLSTATE: HY000 (ER_TRG_NO_DEFINER)

  Message: No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.

- Error: 1455 SQLSTATE: HY000 (ER_OLD_FILE_FORMAT)

  Message: '%s' has an old format, you should re-create the '%s' object(s)

- Error: 1456 SQLSTATE: HY000 (ER_SP_RECURSION_LIMIT)

  Message: Recursive limit %d (as set by the max_sp_recursion_depth variable) was exceeded for routine %s

- Error: 1457 SQLSTATE: HY000 (ER_SP_PROC_TABLE_CORRUPT)

  Message: Failed to load routine %s. The table mysql.proc is missing, corrupt, or contains bad data (internal code %d)

- Error: 1458 SQLSTATE: HY000 (ER_PARTITION_REQUIRES_VALUES_ERROR)

  Message: %s PARTITIONING requires definition of VALUES %s for each partition

- Error: 1459 SQLSTATE: HY000 (ER_PARTITION_WRONG_VALUES_ERROR)

  Message: Only %s PARTITIONING can use VALUES %s in partition definition

- Error: 1460 SQLSTATE: HY000 (ER_PARTITION_MAXVALUE_ERROR)

  Message: MAXVALUE can only be used in last partition definition

- Error: 1461 SQLSTATE: HY000 (ER_PARTITION_SUBPARTITION_ERROR)

  Message: Subpartitions can only be hash partitions and by key

- Error: 1462 SQLSTATE: HY000 (ER_PARTITION_WRONG_NO_PART_ERROR)

  Message: Wrong number of partitions defined, mismatch with previous setting

- Error: 1463 SQLSTATE: HY000 (ER_PARTITION_WRONG_NO_SUBPART_ERROR)

  Message: Wrong number of subpartitions defined, mismatch with previous setting

- Error: 1464 SQLSTATE: HY000 (ER_CONST_EXPR_IN_PARTITION_FUNC_ERROR)

  Message: Constant/Random expression in (sub)partitioning function is not allowed

- Error: 1465 SQLSTATE: HY000 (ER_NO_CONST_EXPR_IN_RANGE_OR_LIST_ERROR)

  Message: Expression in RANGE/LIST VALUES must be constant

- Error: 1466 SQLSTATE: HY000 (ER_FIELD_NOT_FOUND_PART_ERROR)

  Message: Field in list of fields for partition function not found in table

- Error: 1467 SQLSTATE: HY000 (ER_LIST_OF_FIELDS_ONLY_IN_HASH_ERROR)

  Message: List of fields is only allowed in KEY partitions

- Error: 1468 SQLSTATE: HY000 (ER_INCONSISTENT_PARTITION_INFO_ERROR)

  Message: The partition info in the frm file is not consistent with what can be written into the frm file

- Error: 1469 SQLSTATE: HY000 (ER_PARTITION_FUNC_NOT_ALLOWED_ERROR)

  Message: The %s function returns the wrong type

- Error: 1470 SQLSTATE: HY000 (ER_PARTITIONS_MUST_BE_DEFINED_ERROR)

  Message: For %s partitions each partition must be defined

- Error: 1471 SQLSTATE: HY000 (ER_RANGE_NOT_INCREASING_ERROR)

  Message: VALUES LESS THAN value must be strictly increasing for each partition

- Error: 1472 SQLSTATE: HY000 (ER_INCONSISTENT_TYPE_OF_FUNCTIONS_ERROR)

  Message: VALUES value must be of same type as partition function

- Error: 1473 SQLSTATE: HY000 (ER_MULTIPLE_DEF_CONST_IN_LIST_PART_ERROR)

  Message: Multiple definition of same constant in list partitioning

- Error: 1474 SQLSTATE: HY000 (ER_PARTITION_ENTRY_ERROR)

  Message: Partitioning can not be used stand-alone in query

- Error: 1475 SQLSTATE: HY000 (ER_MIX_HANDLER_ERROR)

  Message: The mix of handlers in the partitions is not allowed in this version of MySQL

- Error: 1476 SQLSTATE: HY000 (ER_PARTITION_NOT_DEFINED_ERROR)

  Message: For the partitioned engine it is necessary to define all %s

- Error: 1477 SQLSTATE: HY000 (ER_TOO_MANY_PARTITIONS_ERROR)

  Message: Too many partitions were defined

- Error: 1478 SQLSTATE: HY000 (ER_SUBPARTITION_ERROR)

  Message: It is only possible to mix RANGE/LIST partitioning with HASH/KEY partitioning for subpartitioning

- Error: 1479 SQLSTATE: HY000 (ER_CANT_CREATE_HANDLER_FILE)

  Message: Failed to create specific handler file

- Error: 1480 SQLSTATE: HY000 (ER_BLOB_FIELD_IN_PART_FUNC_ERROR)

  Message: A BLOB field is not allowed in partition function

- Error: 1481 SQLSTATE: HY000 (ER_CHAR_SET_IN_PART_FIELD_ERROR)

  Message: VARCHAR only allowed if binary collation for partition functions

- Error: 1482 SQLSTATE: HY000 (ER_UNIQUE_KEY_NEED_ALL_FIELDS_IN_PF)

  Message: A %s need to include all fields in the partition function
- Error: 1483 SQLSTATE: HY000 (ER_NO_PARTS_ERROR)

  Message: Number of %s = 0 is not an allowed value
- Error: 1484 SQLSTATE: HY000 (ER_PARTITION_MGMT_ON_NONPARTITIONED)

  Message: Partition management on a not partitioned table is not possible
- Error: 1485 SQLSTATE: HY000 (ER_DROP_PARTITION_NON_EXISTENT)

  Message: Error in list of partitions to change
- Error: 1486 SQLSTATE: HY000 (ER_DROP_LAST_PARTITION)

  Message: Cannot remove all partitions, use DROP TABLE instead
- Error: 1487 SQLSTATE: HY000 (ER_COALESCE_ONLY_ON_HASH_PARTITION)

  Message: COALESCE PARTITION can only be used on HASH/KEY partitions
- Error: 1488 SQLSTATE: HY000 (ER_ONLY_ON_RANGE_LIST_PARTITION)

  Message: %s PARTITION can only be used on RANGE/LIST partitions
- Error: 1489 SQLSTATE: HY000 (ER_ADD_PARTITION_SUBPART_ERROR)

  Message: Trying to Add partition(s) with wrong number of subpartitions
- Error: 1490 SQLSTATE: HY000 (ER_ADD_PARTITION_NO_NEW_PARTITION)

  Message: At least one partition must be added
- Error: 1491 SQLSTATE: HY000 (ER_COALESCE_PARTITION_NO_PARTITION)

  Message: At least one partition must be coalesced
- Error: 1492 SQLSTATE: HY000 (ER_REORG_PARTITION_NOT_EXIST)

  Message: More partitions to reorganise than there are partitions
- Error: 1493 SQLSTATE: HY000 (ER_SAME_NAME_PARTITION)

  Message: All partitions must have unique names in the table
- Error: 1494 SQLSTATE: HY000 (ER_CONSECUTIVE_REORG_PARTITIONS)

  Message: When reorganising a set of partitions they must be in consecutive order
- Error: 1495 SQLSTATE: HY000 (ER_REORG_OUTSIDE_RANGE)

  Message: The new partitions cover a bigger range then the reorganised partitions do
- Error: 1496 SQLSTATE: HY000 (ER_DROP_PARTITION_FAILURE)

  Message: Drop partition not supported in this version for this handler
- Error: 1497 SQLSTATE: HY000 (ER_DROP_PARTITION_WHEN_FK_DEFINED)

  Message: Cannot drop a partition when a foreign key constraint is defined on the table
- Error: 1498 SQLSTATE: HY000 (ER_PLUGIN_IS_NOT_LOADED)

Message: Plugin '%s' is not loaded

- Error: 1499 SQLSTATE: HY000 (ER_WRONG_VALUE)

  Message: Incorrect %s value: '%s'

- Error: 1500 SQLSTATE: HY000 (ER_NO_PARTITION_FOR_GIVEN_VALUE)

  Message: Table has no partition for value %ld

- Error: 1501 SQLSTATE: HY000 (ER_BINLOG_ROW_LOGGING_FAILED)

  Message: Writing one row to the row-based binary log failed

- Error: 1502 SQLSTATE: HY000 (ER_BINLOG_ROW_WRONG_TABLE_DEF)

  Message: Table definition on master and slave does not match

- Error: 1503 SQLSTATE: HY000 (ER_BINLOG_ROW_RBR_TO_SBR)

  Message: Slave running with --log-slave-updates must use row-based binary logging to be able to replicate row-based binary log events

B.2. Client Error Codes and Messages

Client error information comes from the following source files:

- The Error values and the symbols in parentheses correspond to definitions in the include/errmsg.h MySQL source file.
- The Message values correspond to the error messages that are listed in the libmysql/errmsg.c file. %d and %s represent numbers and strings, respectively, that are substituted into the messages when they are displayed.

Because updates are frequent, it is possible that these files contain additional error information not listed here.

- Error: 2000 (CR_UNKNOWN_ERROR)

  Message: Unknown MySQL error

- Error: 2001 (CR_SOCKET_CREATE_ERROR)

  Message: Can't create UNIX socket (%d)

- Error: 2002 (CR_CONNECTION_ERROR)

  Message: Can't connect to local MySQL server through socket '%s' (%d)

- Error: 2003 (CR_CONN_HOST_ERROR)

  Message: Can't connect to MySQL server on '%s' (%d)

- Error: 2004 (CR_IPSOCK_ERROR)

  Message: Can't create TCP/IP socket (%d)

- Error: 2005 (CR_UNKNOWN_HOST)

Message: Unknown MySQL server host '%s' (%d)

- Error: 2006 (CR_SERVER_GONE_ERROR)

  Message: MySQL server has gone away

- Error: 2007 (CR_VERSION_ERROR)

  Message: Protocol mismatch; server version = %d, client version = %d

- Error: 2008 (CR_OUT_OF_MEMORY)

  Message: MySQL client ran out of memory

- Error: 2009 (CR_WRONG_HOST_INFO)

  Message: Wrong host info

- Error: 2010 (CR_LOCALHOST_CONNECTION)

  Message: Localhost via UNIX socket

- Error: 2011 (CR_TCP_CONNECTION)

  Message: %s via TCP/IP

- Error: 2012 (CR_SERVER_HANDSHAKE_ERR)

  Message: Error in server handshake

- Error: 2013 (CR_SERVER_LOST)

  Message: Lost connection to MySQL server during query

- Error: 2014 (CR_COMMANDS_OUT_OF_SYNC)

  Message: Commands out of sync; you can't run this command now

- Error: 2015 (CR_NAMEDPIPE_CONNECTION)

  Message: Named pipe: %s

- Error: 2016 (CR_NAMEDPIPEWAIT_ERROR)

  Message: Can't wait for named pipe to host: %s pipe: %s (%lu)

- Error: 2017 (CR_NAMEDPIPEOPEN_ERROR)

  Message: Can't open named pipe to host: %s pipe: %s (%lu)

- Error: 2018 (CR_NAMEDPIPESETSTATE_ERROR)

  Message: Can't set state of named pipe to host: %s pipe: %s (%lu)

- Error: 2019 (CR_CANT_READ_CHARSET)

  Message: Can't initialize character set %s (path: %s)

- Error: 2020 (CR_NET_PACKET_TOO_LARGE)

  Message: Got packet bigger than 'max_allowed_packet' bytes

- Error: 2021 (CR_EMBEDDED_CONNECTION)

Message: Embedded server

- Error: 2022 (CR_PROBE_SLAVE_STATUS)

  Message: Error on SHOW SLAVE STATUS:

- Error: 2023 (CR_PROBE_SLAVE_HOSTS)

  Message: Error on SHOW SLAVE HOSTS:

- Error: 2024 (CR_PROBE_SLAVE_CONNECT)

  Message: Error connecting to slave:

- Error: 2025 (CR_PROBE_MASTER_CONNECT)

  Message: Error connecting to master:

- Error: 2026 (CR_SSL_CONNECTION_ERROR)

  Message: SSL connection error

- Error: 2027 (CR_MALFORMED_PACKET)

  Message: Malformed packet

- Error: 2028 (CR_WRONG_LICENSE)

  Message: This client library is licensed only for use with MySQL servers having '%s' license

- Error: 2029 (CR_NULL_POINTER)

  Message: Invalid use of null pointer

- Error: 2030 (CR_NO_PREPARE_STMT)

  Message: Statement not prepared

- Error: 2031 (CR_PARAMS_NOT_BOUND)

  Message: No data supplied for parameters in prepared statement

- Error: 2032 (CR_DATA_TRUNCATED)

  Message: Data truncated

- Error: 2033 (CR_NO_PARAMETERS_EXISTS)

  Message: No parameters exist in the statement

- Error: 2034 (CR_INVALID_PARAMETER_NO)

  Message: Invalid parameter number

- Error: 2035 (CR_INVALID_BUFFER_USE)

  Message: Can't send long data for non-string/non-binary data types (parameter: %d)

- Error: 2036 (CR_UNSUPPORTED_PARAM_TYPE)

  Message: Using unsupported buffer type: %d (parameter: %d)

- Error: 2037 (CR_SHARED_MEMORY_CONNECTION)

Message: Shared memory: %s

- Error: 2038 (CR_SHARED_MEMORY_CONNECT_REQUEST_ERROR)

  Message: Can't open shared memory; client could not create request event (%lu)

- Error: 2039 (CR_SHARED_MEMORY_CONNECT_ANSWER_ERROR)

  Message: Can't open shared memory; no answer event received from server (%lu)

- Error: 2040 (CR_SHARED_MEMORY_CONNECT_FILE_MAP_ERROR)

  Message: Can't open shared memory; server could not allocate file mapping (%lu)

- Error: 2041 (CR_SHARED_MEMORY_CONNECT_MAP_ERROR)

  Message: Can't open shared memory; server could not get pointer to file mapping (%lu)

- Error: 2042 (CR_SHARED_MEMORY_FILE_MAP_ERROR)

  Message: Can't open shared memory; client could not allocate file mapping (%lu)

- Error: 2043 (CR_SHARED_MEMORY_MAP_ERROR)

  Message: Can't open shared memory; client could not get pointer to file mapping (%lu)

- Error: 2044 (CR_SHARED_MEMORY_EVENT_ERROR)

  Message: Can't open shared memory; client could not create %s event (%lu)

- Error: 2045 (CR_SHARED_MEMORY_CONNECT_ABANDONED_ERROR)

  Message: Can't open shared memory; no answer from server (%lu)

- Error: 2046 (CR_SHARED_MEMORY_CONNECT_SET_ERROR)

  Message: Can't open shared memory; cannot send request event to server (%lu)

- Error: 2047 (CR_CONN_UNKNOW_PROTOCOL)

  Message: Wrong or unknown protocol

- Error: 2048 (CR_INVALID_CONN_HANDLE)

  Message: Invalid connection handle

- Error: 2049 (CR_SECURE_AUTH)

  Message: Connection using old (pre-4.1.1) authentication protocol refused (client option 'secure_auth' enabled)

- Error: 2050 (CR_FETCH_CANCELED)

  Message: Row retrieval was canceled by mysql_stmt_close() call

- Error: 2051 (CR_NO_DATA)

  Message: Attempt to read column without prior row fetch

- Error: 2052 (CR_NO_STMT_METADATA)

  Message: Prepared statement contains no metadata

- Error: 2053 (CR_NO_RESULT_SET)

Message: Attempt to read a row while there is no result set associated with the statement

- Error: `2054` (`CR_NOT_IMPLEMENTED`)

  Message: This feature is not implemented yet

Appendix C. Credits

This appendix lists the developers, contributors, and supporters that have helped to make MySQL what it is today.

C.1. Developers at MySQL AB

These are the developers that are or have been employed by MySQL AB to work on the `MySQL` database software, roughly in the order they started to work with us. Following each developer is a small list of the tasks that the developer is responsible for, or the accomplishments they have made. All developers are involved in support.

- Michael (Monty) Widenius
  - Lead developer and main author of the MySQL server (`mysqld`).
  - New functions for the string library.
  - Most of the `mysys` library.
  - The `ISAM` and `MyISAM` libraries (B-tree index file handlers with index compression and different record formats).
  - The `HEAP` library. A memory table system with our superior full dynamic hashing. In use since 1981 and published around 1984.
  - The `replace` program (take a look at it, it's **COOL**!).
  - Connector/ODBC (MyODBC), the ODBC driver for Windows.
  - Fixing bugs in MIT-pthreads to get it to work for MySQL Server. And also Unireg, a curses-based application tool with many utilities.
  - Porting of `mSQL` tools like `msqlperl`, `DBD/DBI`, and `DB2mysql`.
  - Most of `crash-me` and the foundation for the MySQL benchmarks.
- David Axmark
  - Initial main writer of the **Reference Manual**, including enhancements to `texi2html`.
  - Automatic Web site updating from the manual.
  - Initial Autoconf, Automake, and Libtool support.
  - Licensing.
  - Parts of all the text files. (Nowadays only the `README` is left. The rest ended up in the manual.)
  - Lots of testing of new features.
  - Our in-house Free Software legal expert.
  - Mailing list maintainer (who never has the time to do it right...).
  - Our original portability code (now more than 10 years old). Nowadays only some parts of `mysys` are left.
  - Someone for Monty to call in the middle of the night when he just got that new feature to work.

    - Chief "Open Sourcerer" (MySQL community relations).
- Jani Tolonen
    - `mysqlimport`
    - A lot of extensions to the command-line clients.
    - `PROCEDURE ANALYSE()`
- Sinisa Milivojevic (now in support)
    - Compression (with `zlib`) in the client/server protocol.
    - Perfect hashing for the lexical analyzer phase.
    - Multi-row `INSERT`
    - `mysqldump` -e option
    - `LOAD DATA LOCAL INFILE`
    - `SQL_CALC_FOUND_ROWS` `SELECT` option
    - `--max-user-connections=...` option
    - `net_read` and `net_write_timeout`
    - `GRANT`/`REVOKE` and `SHOW GRANTS FOR`
    - New client/server protocol for 4.0
    - `UNION` in 4.0
    - Multiple-table `DELETE`/`UPDATE`
    - Subqueries in the `FROM` clause (4.1).
    - User resources management
    - Initial developer of the `MySQL++` C++ API and the `MySQLGUI` client.
- Tonu Samuel (past developer)
    - VIO interface (the foundation for the encrypted client/server protocol).
    - MySQL Filesystem (a way to use MySQL databases as files and directories).
    - The `CASE` expression.
    - The `MD5()` and `COALESCE()` functions.
    - `RAID` support for `MyISAM` tables.
- Sasha Pachev (past developer)
    - Initial implementation of replication (up to version 4.0).
    - `SHOW CREATE TABLE`.
    - `mysql-bench`
- Matt Wagner

    - MySQL test suite.
    - Webmaster (until 2002).
- Miguel Solorzano (now in support)
    - Win32 development and release builds.
    - Windows NT server code.
    - WinMySQLAdmin
- Timothy Smith (now in support)
    - Dynamic character sets support.
    - configure, RPMs and other parts of the build system.
    - Initial developer of `libmysqld`, the embedded server.
- Sergei Golubchik
    - Full-text search.
    - Added keys to the `MERGE` library.
    - Precision math.
- Jeremy Cole (past developer)
    - Proofreading and editing this fine manual.
    - `ALTER TABLE ... ORDER BY ...`.
    - `UPDATE ... ORDER BY ...`.
    - `DELETE ... ORDER BY ...`.
- Indrek Siitan
    - Designing/programming of our Web interface.
    - Author of our newsletter management system.
- Jorge del Conde (now in support)
    - `MySQLCC` (`MySQL Control Center`)
    - Win32 development
    - Initial implementation of the Web site portals.
- Venu Anuganti (past developer)
    - MyODBC 3.51
    - New client/server protocol for 4.1 (for prepared statements).
- Arjen Lentz (now handling community)
    - Maintainer of the MySQL Reference Manual.
    - Preparing the O'Reilly printed edition of the manual.

- Alexander (Bar) Barkov, Alexey (Holyfoot) Botchkov, and Ramil Kalimullin
  - Spatial data (GIS) and R-Trees implementation for 4.1
  - Unicode and character sets for 4.1; documentation for same
- Oleksandr (Sanja) Byelkin
  - Query cache in 4.0
  - Implementation of subqueries (4.1).
  - Implementation of views (5.0).
- Aleksey (Walrus) Kishkin and Alexey (Ranger) Stroganov
  - Benchmarks design and analysis.
  - Maintenance of the MySQL test suite.
- Zak Greant (past employee)
  - Open Source advocate, MySQL community relations.
- Carsten Pedersen
  - The MySQL Certification program.
- Lenz Grimmer
  - Production (build and release) engineering.
- Peter Zaitsev
  - `SHA1()`, `AES_ENCRYPT()` and `AES_DECRYPT()` functions.
  - Debugging, cleaning up various features.
- Alexander (Salle) Keremidarski
  - Support.
  - Debugging.
- Per-Erik Martin
  - Lead developer for stored procedures (5.0).
- Jim Winstead
  - Former lead Web developer.
  - Improving server, fixing bugs.
- Mark Matthews
  - Connector/J driver (Java).
- Peter Gulutzan
  - SQL standards compliance.
  - Documentation of existing MySQL code/algorithms.
  - Character set documentation.

- Guilhem Bichot
  - Replication, from `MySQL` version 4.0.
  - Fixed handling of exponents for `DECIMAL`.
  - Author of `mysql_tableinfo`.
  - Backup (in 5.1).
- Antony T. Curtis
  - Porting of the MySQL Database software to OS/2.
- Mikael Ronstrom
  - Much of the initial work on NDB Cluster until 2000. Roughly half the code base at that time. Transaction protocol, node recovery, system restart and restart code and parts of the API functionality.
  - Lead Architect, developer, debugger of NDB Cluster 1994-2004
  - Lots of optimizations
- Jonas Oreland
  - On-line Backup
  - The automatic test environment of MySQL Cluster
  - Portability Library for NDB Cluster
  - Lots of other things
- Pekka Nouisiainen
  - Ordered index implementation of MySQL Cluster
  - BLOB support in MySQL Cluster
  - Charset support in MySQL Cluster
- Martin Skold
  - Unique index implementation of MySQL Cluster
  - Integration of NDB Cluster into MySQL
- Magnus Svensson
  - The test framework for MySQL Cluster
  - Integration of NDB Cluster into MySQL
- Tomas Ulin
  - Lots of work on configuration changes for simple installation and use of MySQL Cluster
- Konstantin Osipov
  - Prepared statements.
  - Cursors.
- Dmitri Lenev

- Time zone support.
- Triggers (in 5.0).

C.2. Contributors to MySQL

Although MySQL AB owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola `<qwerg@mbox.vol.it>` or `<qwerg@tin.it>`

  The initial port to Win32/NT.

- Per Eric Olsson

  For more or less constructive criticism and real testing of the dynamic record format.

- Irena Pancirov `<irena@mail.yacc.it>`

  Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`

- David J. Hughes

  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with `mSQL`, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql` client are programs that were largely influenced by their `mSQL` counterparts. We have put a lot of effort into making the MySQL syntax a superset of `mSQL`. Many of the API's ideas are borrowed from `mSQL` to make it easy to port free `mSQL` programs to the MySQL API. The MySQL software doesn't contain any code from `mSQL`. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (non-copyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

  For helping us acquire http://www.mysql.com/.

- Fred Lindberg

  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko `<igor@frog.kiev.ua>`

  `mysqldump` (previously `msqldump`, but ported and enhanced by Monty).

- Yuri Dario

  For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

  Author of `mysqlhotcopy`.

- Zarko Mocnik `<zarko.mocnik@dem.si>`

  Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>

  The _MB character set macros and the ujis and sjis character sets.

- Joshua Chamas <joshua@chamas.com>

  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <Yves.Carlier@rug.ac.be>

  mysqlaccess, a program to show the access rights for a user.

- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)

  For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>

  Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>

  For setting up a searchable mailing list archive at his site.

- Rick Mehalick <Rick_Mehalick@i-o.com>

  For xmysql, a graphical X client for MySQL Server.

- Doug Sisk <sisk@wix.com>

  For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <axeld@vial.ethz.ch>

  For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <toni@readysoft.es>

  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <jay@pathways.sde.state.sc.us>

  For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>

  Ideas for secure checking of DNS hostnames.

- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>

  Some support for Chinese(BIG5) characters.

- Wei He <hewei@mail.ied.ac.cn>

  A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <adelton@fi.muni.cz>

  Czech sorting order.

- Zeev Suraski <bourbon@netvision.net.il>

  FROM_UNIXTIME() time formatting, ENCRYPT() functions, and bison advisor. Active mailing list member.

- Luuk de Boer <luuk@wxs.nl>

  Ported (and extended) the benchmark suite to DBI/DBD. Have been of great help with crash-me and running benchmarks. Some new date functions. The mysql_setpermission script.

- Alexis Mikhailov <root@medinf.chuvashia.su>

  User-defined functions (UDFs); CREATE FUNCTION and DROP FUNCTION.

- Andreas F. Bobak <bobak@relog.ch>

  The AGGREGATE extension to user-defined functions.

- Ross Wakelin <R.Wakelin@march.co.uk>

  Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III <jetman@li.net>

  The libmysql.dll library.

- James Pereria <jpereira@iafrica.com>

  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- Curt Sampson <cjs@portal.ca>

  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- Martin Ramsch <m.ramsch@computer.org>

  Examples in the MySQL Tutorial.

- Steve Harvey

  For making mysqlaccess more secure.

- Konark IA-64 Centre of Persistent Systems Private Limited

  http://www.pspl.co.in/konark/. Help with the Win64 port of the MySQL server.

- Albert Chin-A-Young.

  Configure updates for Tru64, large file support and better TCP wrappers support.

- John Birrell

  Emulation of pthread_mutex() for OS/2.

- Benjamin Pflugmann

  Extended MERGE tables to handle INSERTS. Active member on the MySQL mailing lists.

- Jocelyn Fournier

  Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- Marc Liyanage

  Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X PKGs.

- Robert Rutherford

Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

  Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>

  Irix setup.

- Luuk de Boer <luuk@wxs.nl>

  Benchmark questions.

- Tim Sailer <tps@users.buoy.com>

  DBD::mysql questions.

- Boyd Lynn Gerber <gerberb@zenez.com>

  SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>

  xmysql-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>

  Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>

  General questions.

- Jonathan J Smith <jsmith@wtp.net>

  Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>

  Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>

Is flexible and can handle Linux and perhaps HP-UX. Tries to get users to use `mysqlbug`.

- John Lyon <jlyon@imag.net>

  Questions about installing MySQL on Linux systems, using either `.rpm` files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>

  Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>

  ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>

  `DBD`, Linux, some SQL syntax questions.

C.3. Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois

  Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

  Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

  For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (http://mysql.hitstar.com/) versions were based. Personal home page at linuxdb.yeah.net [http://linuxdb.yeah.net].

- Jay Flaherty <fty@mediapulse.com>

  Big parts of the Perl `DBI`/`DBD` section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

  Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>

  French error messages.

- Petr Snajdr, <snajdr@pvt.net>

  Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>

Polish error messages.

- Miguel Angel Fernandez Roiz

  Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>

  Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>

  Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>

  Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>

  German error messages.

- Billik Stefan <billik@sun.uniag.sk>

  Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

  Romanian error messages.

- Peter Feher

  Hungarian error messages.

- Roberto M. Serqueira

  Portuguese error messages.

- Carsten H. Pedersen

  Danish error messages.

- Arjen G. Lentz

  Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

C.4. Libraries used by and included with MySQL

The following is a list of the creators of the libraries we have included with the MySQL server source to make it easy to compile and install MySQL. We are very thankfully to all individuals that have created these and it has made our life much easier.

- Fred Fish

  For his excellent C debugging and trace library. Monty has made a number of smaller improvements to the library (speed and additional options).

- Richard A. O'Keefe

  For his public domain string library.

- Henry Spencer

  For his regex library, used in `WHERE column REGEXP regexp`.

- Chris Provenzano

  Portable user level pthreads. From the copyright: This product includes software developed by Chris Provenzano, the University of California, Berkeley, and contributors. We are currently using version 1_60_beta6 patched by Monty (see `mit-pthreads/Changes-mysql`).

- Jean-loup Gailly and Mark Adler

  For the zlib library (used on MySQL on Windows).

- Bjorn Benson

  For his safe_malloc (memory checker) package which is used in when you configure MySQL with `--debug`.

- Free Software Foundation

  The `readline` library (used by the `mysql` command-line client).

- The NetBSD foundation

  The `libedit` package (optionally used by the `mysql` command-line client).

C.5. Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We can't list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at http://solutions.mysql.com/software/.

- Tim Bunce, Alligator Descartes

  For the `DBD` (Perl) interface.

- Andreas Koenig `<a.koenig@mind.de>`

  For the Perl interface for MySQL Server.

- Jochen Wiedmann `<wiedmann@neckar-alb.de>`

  For maintaining the Perl `DBD::mysql` module.

- Eugene Chan `<eugene@acenet.com.sg>`

  For porting PHP for MySQL Server.

- Georg Richter

  MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli `<maruzz@matrice.it>`

For porting iODBC (Unix ODBC).

- Xavier Leroy <Xavier.Leroy@inria.fr>

  The author of LinuxThreads (used by the MySQL Server on Linux).

C.6. Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

  From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb` and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

  For a really great editor/environment used by almost everybody at MySQL AB.

- Julian Seward

  Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

  For `DDD` (The Data Display Debugger) which is an excellent graphical front end to `gdb`).

C.7. Supporters of MySQL

Although MySQL AB owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

  Funded replication.

- NuSphere

  Editing of the MySQL manual.

- Stork Design studio

  The MySQL Web site in use between 1998-2000.

- Intel

  Contributed to development on Windows and Linux platforms.

- Compaq

  Contributed to Development on Linux/Alpha.

- SWSoft

  Development on the embedded `mysqld` version.

- FutureQuest

  `--skip-show-database`

Appendix D. MySQL Change History

This appendix lists the changes from version to version in the MySQL source code through the latest version of MySQL 5.1, which is currently MySQL 5.1.5-alpha. Starting with MySQL 5.0, we began offering a new version of the Manual for each new series of MySQL releases (5.0, 5.1, and so on). For information about changes in previous release series of the MySQL database software, see the corresponding version of this Manual. For information about legacy versions of the MySQL software through the 4.1 series, see *MySQL 4.1 Reference Manual*.

We update this section as we add new features in the 5.1 series, so that everybody can follow the development process.

Note that we tend to update the manual at the same time we make changes to MySQL. If you find a recent version of MySQL listed here that you can't find on our download page (http://dev.mysql.com/downloads/), it means that the version has not yet been released.

The date mentioned with a release version is the date of the last BitKeeper ChangeSet on which the release was based, not the date when the packages were made available. The binaries are usually made available a few days after the date of the tagged ChangeSet, because building and testing all packages takes some time.

The manual included in the source and binary distributions may not be fully accurate when it comes to the release changelog entries, because the integration of the manual happens at build time. For the most up-to-date release changelog, please refer to the online version instead.

D.1. Changes in release 5.1.x (Development)

The following changelog shows what has been done in the 5.1 tree:

- MySQL 5.1 implements support for a plugin API that allows the loading and unloading of components at runtime, without restarting the server. Section 27.2, “The MySQL Plugin Interface”.

For a full list of changes, please refer to the changelog sections for each individual 5.1.x release.

D.1.1. Changes in release 5.1.5 (Not yet released)

Functionality added or changed:

- Added the `--base64-output` option to `mysqlbinlog` to print all binary log entries using base64 encoding. This is for debugging only. Logs produced using this option should not be applied on production systems.
- Added the `--port-open-timeout` option to `mysqld` to control how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. (Bug #15591 [http://bugs.mysql.com/15591])
- Two new Hungarian collations are included: `utf8_hungarian_ci` and `ucs2_hungarian_ci`. These support the correct sort order for Hungarian vowels. However, they do not support the correct order for sorting Hungarian consonant contractions; this issue will be fixed in a future release.

Bugs fixed:

- `InnoDB`: Comparison of indexed `VARCHAR CHARACTER SET ucs2 COLLATE ucs2_bin` columns using `LIKE` could fail. (Bug #14583 [http://bugs.mysql.com/14583])

- Creating a trigger caused a server crash if the table or trigger database was not known because no default database had been selected. (Bug #14863 [http://bugs.mysql.com/14863])

- Issuing a `DROP USER` command could cause some users to encounter a *`hostname`* `is not allowed to connect to this MySQL server` error. (Bug #15775 [http://bugs.mysql.com/15775])

- The `--plugin_dir` option was not working. Also fix error with specifying parser name for fulltext. (Bug #16068 [http://bugs.mysql.com/16068])

- Attempting to insert into a table partitioned by `LIST` a value less than any specified in one of the table's partition definitions resulted in a server crash. In such cases, `mysqld` now returns ERROR 1500 (HY000): Table has no partition for value *`v`*, where *`v`* is the out-of-range value. (Bug #15819 [http://bugs.mysql.com/15819])

D.1.2. Changes in release 5.1.4 (21 December 2005)

Functionality added or changed:

- Added the `--server-id` option to `mysqlbinlog` to enable only those events created by the server having the given server ID to be extracted. (Bug #15485 [http://bugs.mysql.com/15485])

- It is now possible to build the server such that `MyISAM` tables can support up to 128 keys rather than the standard 64. This can be done by configuring the build using the option `--with-max-indexes=`*`N`*, where *`N`*#128 is the maximum number of indexes to permit per table. (Bug #10932 [http://bugs.mysql.com/10932])

- The bundled `BDB` library was upgraded to version 4.4.16.

- Added the `cp1250_polish_ci` collation for the `cp1250` character set.

- Added the `myisam_use_mmap` system variable.

- Added the `--bdb-data-direct` and `--bdb-log-direct` server options.

Bugs fixed:

- `BDB`: A `DELETE`, `INSERT`, or `UPDATE` of a `BDB` table could cause the server to crash where the query contained a subquery using an index read. (Bug #15536 [http://bugs.mysql.com/15536])

- A left join on a column that having a `NULL` value could cause the server to crash. (Bug #15268 [http://bugs.mysql.com/15268])

- It was not possible to reorganize a partition reusing a discarded partition name.

  Now, for example, you can create a table such as this one:

  ```
  CREATE TABLE t1 (a INT)
      PARTITION BY RANGE (a) (
        PARTITION p0 VALUES LESS THAN (10),
        PARTITION p1 VALUES LESS THAN (20),
        PARTITION p2 VALUES LESS THAN MAXVALUE
      );
  ```

  and then repartition it as shown here:

  ```
  ALTER TABLE t1 REORGANIZE PARTITION p2 INTO (
      PARTITION p2 VALUES LESS THAN (30)
  ```

```
);
```

Previously, attempting to do so would produce the error All partitions must have unique names in the table. (Bug #15521 [http://bugs.mysql.com/15521])

- NDB Cluster: The --ndb option for perror did not function. (Bug #15486 [http://bugs.mysql.com/15486])
- The BLACKHOLE storage engine did not handle transactions properly: Rolled-back transactions were written to the binary log. Now they ae not. (Bug #15406 [http://bugs.mysql.com/15406])
- NDB Cluster: Using ORDER BY *primary_key_column* when selecting from a table having the primary key on a VARCHAR column caused a forced shutdown of the cluster. (Bug #14828 [http://bugs.mysql.com/14828], Bug #15240 [http://bugs.mysql.com/15240], Bug #15682 [http://bugs.mysql.com/15682], Bug #15517 [http://bugs.mysql.com/15517])
- ANALYZE TABLE did not properly update table statistics for a MyISAM table with a FULL-TEXT index containing stopwords, so a subsequent ANALYZE TABLE would not recognize the table as having already been analyzed. (Bug #14902 [http://bugs.mysql.com/14902])
- The maximum value of MAX_ROWS was handled incorrectly on 64-bit systems. (Bug #14155 [http://bugs.mysql.com/14155])
- Multiple-table update operations were counting updates and not updated rows. As a result, if a row had several updates it was counted several times for the “rows matched” value but updated only once. (Bug #15028 [http://bugs.mysql.com/15028])
- SELECT queries that began with an opening parenthesis were not being placed in the query cache. (Bug #14652 [http://bugs.mysql.com/14652])
- Space truncation was being ignored when inserting into BINARY or VARBINARY columns. Now space truncation results in a warning, or an error in strict mode. (Bug #14299 [http://bugs.mysql.com/14299])
- Selecting from a view processed with the temptable algorithm caused a server crash if the query cache was enabled. (Bug #15119 [http://bugs.mysql.com/15119])
- Creating a view that referenced a stored function that selected from a view caused a crash upon selection from the view. (Bug #15096 [http://bugs.mysql.com/15096])
- Creating a view within a stored procedure could result in an out of memory error or a server crash. (Bug #14885 [http://bugs.mysql.com/14885])
- SHOW CREATE DATABASE was sometimes refused when the client had privileges for the database. (Bug #9785 [http://bugs.mysql.com/9785])
- mysql ignored the MYSQL_TCP_PORT environment variable. (Bug #5792 [http://bugs.mysql.com/5792])
- ROW_COUNT() returned an incorrect result after EXECUTE of a prepared statement. (Bug #14956 [http://bugs.mysql.com/14956])
- Invalid casts to DATE values now result in a message of Incorrect datetime value, rather than Truncated incorrect datetime value. (Bug #8294 [http://bugs.mysql.com/8294])
- Attempts to assign NULL to a NOT NULL column in strict mode now result in a message of Column '*col_name*' cannot be null, rather than Column set to default value; NULL supplied to NOT NULL column '*col_name*' at row *n*. (Bug #11491 [http://bugs.mysql.com/11491])
- For binary string data types, mysqldump --hex-blob produced an illegal output value of

`0x` rather than `''`. (Bug #13318 [http://bugs.mysql.com/13318])

- Some comparisons for the `IN()` operator were inconsistent with equivalent comparisons for the `=` operator. (Bug #12612 [http://bugs.mysql.com/12612])

D.1.3. Changes in release 5.1.3 (29 November 2005)

Functionality added or changed:

This is the first public alpha release of the current MySQL 5.1 development branch, providing an insight to upcoming features. Although some of these are still under heavy development, this release includes the following new features and changes (in comparison to the current MySQL 5.0 production release):

- **Partitioning**: allows distributing portions of individual tables across a filesystem, according to rules which can be set when the table is created. In effect, different portions of a table are stored as separate tables in different locations, but from the user point of view, the partitioned table is still a single table. See Chapter 18, *Partitioning*, for further information on this functionality. (Author: Mikael Ronström)

- **Plugin API**: MySQL 5.1 adds support for a very flexible plugin API that enables loading and unloading of various components at runtime, without restarting the server. Although the work on this is not finished yet, *plugin full-text parsers* are a first step in this direction. This allows users to implement their own input filter on the indexed text, enabling full-text search capability on arbitrary data such as PDF files or other document formats. A pre-parser full-text plugin performs the actual parsing and extraction of the text and hands it over to the built-in MySQL full-text search. (Author: Sergey Vojtovich)

  The plugin API requires the `mysql.plugin` table. When upgrading from an older version of MySQL, you should run the `mysql_fix_privilege_tables` command to create this table. See Section 2.10.2, “Upgrading the Grant Tables”.

  Incompatible change: Plugins are installed in the directory named by the `plugin_dir` system variable. This variable also controls the location from which the server loads user-defined functions (UDFs), which is a change from earlier versions of MySQL. That is, all UDF library files now must be installed in the plugin directory. When upgrading from an older version of MySQL, you must migrate your UDF files to the plugin directory.

- **The Instance Manager (IM)** now has some additional functionality:

  - `SHOW` *`instance_name`* `LOG FILES` provides a listing of all log files used by the instance. (Author: Petr Chardin)

  - `SHOW` *`instance_name`* `LOG {ERROR | SLOW | GENERAL}` *`size`* retrieves a part of the specified log file. (Author: Petr Chardin)

  - `SET` *`instance_name. option_name=option_value`* sets an option to the specified value and writes it to the config file See Section 5.2, “mysqlmanager — The MySQL Instance Manager”, for more details on these new commands. (Author: Petr Chardin)

- The performance of boolean full-text searches (using the “+” Operator) has been improved. See Section 12.7, “Full-Text Search Functions”, for more details about full-text searching. (Author: Sergey Vojtovich)

- `VARCHAR` fields used in MySQL Cluster tables are now variable-sized; that is, they now only allocate as much space as required to store the data. Previously, a `VARCHAR(`*`n`*`)` column allocated n+2 bytes (aligned to 4 bytes), regardless if the actual inserted value required that much space. (In other words, a `VARCHAR` column always required the same, fixed, amount of storage as a `CHAR` column of the same size.)

- Renamed the `table_cache` system variable to `table_open_cache`. Any scripts that refer

to `table_cache` should be updated to use the new name.

- Added the `table_definition_cache` system variable. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache.

Bugs fixed:

- Set functions could not be aggregated in outer subqueries. (Bug #12762 [http://bugs.mysql.com/12762])

D.1.4. Changes in release 5.1.2 (Not released)

Functionality added or changed:

- Added `MAXLOCKS`, `MINLOCKS`, `MAXWRITE`, and `MINWRITE` as allowable values of the `--bdb-lock-detect` option. (Bug #14876 [http://bugs.mysql.com/14876])
- Added the `bdb_cache_parts` and `bdb_region_size` system variables, and allowed `bdb_cache_size` to be larger than 4GB on systems that support it. (Bug #14895 [http://bugs.mysql.com/14895])
- Added `Transactions`, `XA`, and `Savepoints` columns to `SHOW ENGINES` output.
- Added `--replace` to `mysqldump`. This option uses `REPLACE INTO`, rather than `INSERT INTO`, when writing the dumpfile.

Bugs fixed:

- Foreign keys were not properly enforced in `TEMPORARY` tables. Foreign keys now are disallowed in `TEMPORARY` tables. (Bug #12084 [http://bugs.mysql.com/12084])

D.1.5. Changes in release 5.1.1 (Not released)

Functionality added or changed:

Bugs fixed:

- Performing a `CREATE TABLE` statement with a `PARTITION BY` clause in a prepared statement could crash a server running in debug mode. (Bug #12097 [http://bugs.mysql.com/12097])
- `NDB`: Specifying the wrong nodegroup in a `CREATE TABLE` using partitioning would lead to the table name being locked after the `CREATE TABLE` statement failed (that is, the table name could not be re-used). (Bug #12114 [http://bugs.mysql.com/12114])
- Using `ORDER BY` in a query with a partitioned table on a 64-bit operating system could crash the server. (Bug #12116 [http://bugs.mysql.com/12116])
- When two threads compete for the same table, a deadlock could occur if one thread has also a lock on another table through `LOCK TABLES` and the thread is attempting to remove the table in some manner and the other thread want locks on both tables. (Bug #10600 [http://bugs.mysql.com/10600])

D.2. Changes in MyODBC

D.2.1. Changes in MyODBC 3.51.13

Functionality added or changed:

- N/A

Bugs fixed:

- The `SQLDriverConnect()` ODBC method did not work with recent MyODBC releases. (Bug #12393 [http://bugs.mysql.com/12393])

D.2.2. Changes in MyODBC 3.51.12

Functionality added or changed:

- N/A

Bugs fixed:

- `SQLColumns()` returned no information for tables that had a column named using a reserved word. (Bug #9539 [http://bugs.mysql.com/9539])

D.2.3. Changes in MyODBC 3.51.11

Functionality added or changed: No changes.

Bugs fixed:

- `mysql_list_dbcolumns()` and `insert_fields()` were retrieving all rows from a table. Fixed the queries generated by these functions to return no rows. (Bug #8198 [http://bugs.mysql.com/8198])
- `SQLGetTypoInfo()` returned `tinyblob` for `SQL_VARBINARY` and nothing for `SQL_BINARY`. Fixed to return `varbinary` for `SQL_VARBINARY`, `binary` for `SQL_BINARY`, and `longblob` for `SQL_LONGVARBINARY`. (Bug #8138 [http://bugs.mysql.com/8138])

Appendix E. Porting to Other Systems

This appendix helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See Section 2.1.1, “Operating Systems Supported by MySQL”. If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (http://www.mysql.com/), recommending it to other users.

Note: If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server. On Solaris 2.5 we use Sun PThreads (the native thread support in 2.4 and earlier versions is not good enough), on Linux we use LinuxThreads by Xavier Leroy, <Xavier.Leroy@inria.fr>.

The hard part of porting to a new Unix variant without good native thread support is probably to port MIT-pthreads. See `mit-pthreads/README` and Programming POSIX Threads (http://www.humanfactor.com/pthreads/).

Up to MySQL 4.0.2, the MySQL distribution included a patched version of Chris Provenzano's Pthreads from MIT (see the MIT Pthreads Web page at http://www.mit.edu/afs/sipb/project/pthreads/ and a programming introduction at http://www.mit.edu:8001/people/proven/IAP_2000/). These can be used for some operating systems that do not have POSIX threads. See Section 2.8.5, “MIT-pthreads Notes”.

It is also possible to use another user level thread package named FSU Pthreads (see http://moss.csc.ncsu.edu/~mueller/pthreads/). This implementation is being used for the SCO port.

See the `thr_lock.c` and `thr_alarm.c` programs in the `mysys` directory for some tests/examples of these problems.

Both the server and the client need a working C++ compiler. We use `gcc` on many platforms. Other compilers that are known to work are SPARCworks, Sun Forte, Irix `cc`, HP-UX `aCC`, IBM AIX `xlC_r`), Intel `ecc/icc` and Compaq `cxx`).

To compile only the client use `./configure --without-server`.

There is currently no support for only compiling the server, nor is it likely to be added unless someone has a good reason for it.

If you want/need to change any `Makefile` or the configure script you also need GNU Automake and Autoconf. See Section 2.8.3, “Installing from the Development Source Tree”.

All steps needed to remake everything from the most basic files.

```
/bin/rm */.deps/*.P
/bin/rm -f config.cache
aclocal
autoheader
aclocal
automake
autoconf
./configure --with-debug=full --prefix='your installation directory'

# The makefiles generated above need GNU make 3.75 or newer.
# (called gmake below)
gmake clean all install init-db
```

If you run into problems with a new port, you may have to do some debugging of MySQL! See Section E.1, “Debugging a MySQL Server”.

Note: Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to

work!

E.1. Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality) or with `--safe-mode` which disables a lot of optimization that may cause problems. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

If `mysqld` doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults ...`.

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients can't connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See Chapter 5, *Database Administration*. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.12, “Operating System-Specific Notes”.

E.1.1. Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `--with-debug` or the `--with-debug=full` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If you are using `gcc` or `egcs`, the recommended `configure` line is:

```
CC=gcc CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors \
   -fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql \
   --with-debug --with-extra-charsets=complex
```

This avoids problems with the `libstdc++` library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (`SAFEMALLOC`) checker. However, running with `SAFEMALLOC` is quite slow, so if you get performance problems you should start `mysqld` with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If `mysqld` stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` variables above and not use `--with-debug`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `safe_mysqld` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you

should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See Section 1.7.1, “MySQL Mailing Lists”. If you believe that you have found a bug, please use the instructions at Section 1.8, “How to Report Bugs or Problems”.

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

E.1.2. Creating Trace Files

If the `mysqld` server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it's compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld` as of MySQL 4.1.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `C:\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

Note that the trace file become **very big**! If you want to generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:O,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can ftp the trace file, together with a full bug report, to ftp://ftp.mysql.com/pub/mysql/upload/ so that a MySQL developer can take a look a this.

The trace file is made with the **DBUG** package by Fred Fish. See Section E.3, “The DBUG Package”.

E.1.3. Debugging `mysqld` under gdb

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. We recommend you to upgrade to gdb 5.1 ASAP as thread debugging works much better with this version!

NTPL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

In MySQL 4.0.14 and above you should use the `--gdb` option to mysqld. This installs an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It's very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `-O thread_cache_size= 'max_connections +1'`. In most cases just using `-O thread_cache_size=5'` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a SIGSEGV signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb>   backtrace full
gdb>   exit
```

See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with `gdb`, you should download gdb 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug mysqld:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the above output in a bug report, which you can file using the instructions in Section 1.8, “How to Report Bugs or Problems”.

If `mysqld` hangs you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

E.1.4. Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See Section 5.11.1, “The Error Log”. To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to gcc. See Section E.1.1, “Compiling MySQL for Debugging”.

If the error file contains something like the following:

```
mysqld got signal 11;
The manual section 'Debugging a MySQL server' tells you how to use a
stack trace and/or the core file to produce a readable backtrace that may
help in finding out why mysqld died
Attempting backtrace. You can use the following information to find out
where mysqld died.  If you see no messages after this, something went
terribly wrong...
stack range sanity check, ok, backtrace follows
0x40077552
0x81281a0
0x8128f47
0x8127be0
0x8127995
0x8104947
0x80ff28f
0x810131b
0x80ee4bc
0x80c3c91
0x80c6b43
0x80c1fd9
0x80c1686
```

you can find where `mysqld` died by doing the following:

1. Copy the preceding numbers to a file, for example `mysqld.stack`.

2. Make a symbol file for the `mysqld` server:

   ```
   nm -n libexec/mysqld > /tmp/mysqld.sym
   ```

   Note that most MySQL binary distributions (except for the "debug" packages, where this information is included inside of the binaries themselves) ship with the above file, named `mysqld.sym.gz`. In this case, you can simply unpack it by doing:

   ```
   gunzip < bin/mysqld.sym.gz > /tmp/mysqld.sym
   ```

3. Execute `resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack`.

   This prints out where `mysqld` died. If this doesn't help you find out why `mysqld` died, you should make a bug report and include the output from the above command with the bug report.

   Note however that in most cases it does not help us to just have a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, we would in most cases need to know the query that killed `mysqld` and preferable a test case so that we can repeat the problem! See Section 1.8, “How to Report Bugs or Problems”.

E.1.5. Using Log Files to Find Cause of Errors in `mysqld`

Note that before starting `mysqld` with `--log` you should check all your tables with `myisamchk`. See Chapter 5, *Database Administration*.

If `mysqld` dies or hangs, you should start `mysqld` with `--log`. When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you are using `--log` without a file name, the log is stored in the database directory as *`host_name`*`.log` In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See Section 7.2.1, "`EXPLAIN` Syntax (Get Information About a `SELECT`)".

You can find the queries that take a long time to execute by starting `mysqld` with `--log-slow-queries`. See Section 5.11.4, "The Slow Query Log".

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, *Database Administration*), and test the queries in the MySQL log files to see if one doesn't work. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at http://lists.mysql.com/, which also has links to online list archives.

If you have started `mysqld` with `myisam-recover`, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file `'Warning: Checking table ...'` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.3.1, "`mysqld` Command-Line Options".

It's not a good sign if `mysqld` did die unexpectedly, but in this case one shouldn't investigate the `Checking table...` messages but instead try to find out why `mysqld` died.

E.1.6. Making a Test Case If You Experience Table Corruption

If you get corrupted tables or if `mysqld` always fails after some update commands, you can test whether this bug is reproducible by doing the following:

- Take down the MySQL daemon (with `mysqladmin shutdown`).
- Make a backup of the tables (to guard against the very unlikely case that the repair does something bad).
- Check all tables with `myisamchk -s database/*.MYI`. Repair any wrong tables with `myisamchk -r database/`*`table`*`.MYI`.
- Make a second backup of the tables.
- Remove (or move away) any old log files from the MySQL data directory if you need more space.
- Start `mysqld` with `--log-bin`. See Section 5.11.3, "The Binary Log". If you want to find a query that crashes `mysqld`, you should use `--log --log-bin`.
- When you have gotten a crashed table, stop the `mysqld server`.
- Restore the backup.
- Restart the `mysqld` server **without** `--log-bin`

- Re-execute the commands with `mysqlbinlog update-log-file | mysql`. The update log is saved in the MySQL database directory with the name `hostname-bin.#`.

- If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found reproducible bug that should be easy to fix! FTP the tables and the binary log to ftp://ftp.mysql.com/pub/mysql/upload/ and enter it into our bugs system at http://bugs.mysql.com/. (Please note that the `/pub/mysql/upload/` FTP directory is not listable, so you'll not see what you've uploaded in your FTP client.) If you are a support customer, you can use the MySQL Customer Support Center https://support.mysql.com/ to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

E.2. Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See Section 2.8.2, “Typical `configure` Options”.

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.8, “How to Report Bugs or Problems”.

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

E.3. The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is debugging. See Section E.1.2, “Creating Trace Files”.

This section summaries the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `dbug` directory of MySQL source distributions. It's best to use a recent distribution for MySQL 5.1 to get the most updated DBUG manual.

You use the debug package by invoking a program with the `--debug="..."` or the `-#...` option.

Most MySQL programs have a default debug string that is used if you don't specify an option to `--debug`. The default trace file is usually `/tmp/program_name.trace` on Unix and `\program_name.trace` on Windows.

The debug control string is a sequence of colon-separated fields as follows:

```
<field_1>:<field_2>:...:<field_N>
```

Each field consists of a mandatory flag character followed by an optional ‘,’ and comma-separated list of modifiers:

```
flag[,modifier,modifier,...,modifier]
```

The currently recognized flag characters are:

Flag	Description
d	Enable output from DBUG_<N> macros for the current state. May be followed by a list of keywords which selects output only for the DBUG macros with that keyword. An empty list of keywords implies output for all macros.
D	Delay after each debugger output line. The argument is the number of tenths of seconds to delay, subject to machine capabilities. For example, `-#D,20` specifies a delay of two seconds.
f	Limit debugging, tracing, and profiling to the list of named functions. Note that a null list disables all functions. The appropriate `d` or `t` flags must still be given; this flag only limits their actions if they are enabled.
F	Identify the source file name for each line of debug or trace output.
i	Identify the process with the PID or thread ID for each line of debug or trace output.
g	Enable profiling. Create a file called `dbugmon.out` containing information that can be used to profile the program. May be followed by a list of keywords that select profiling only for the functions in that list. A null list implies that all functions are considered.
L	Identify the source file line number for each line of debug or trace output.
n	Print the current function nesting depth for each line of debug or trace output.
N	Number each line of debug output.
o	Redirect the debugger output stream to the specified file. The default output is `stderr`.
O	Like `o`, but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
p	Limit debugger actions to specified processes. A process must be identified with the `DBUG_PROCESS` macro and match one in the list for debugger actions to occur.
P	Print the current process name for each line of debug or trace output.
r	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
S	Do function `_sanity(_file_,_line_)` at each debugged function until `_sanity()` returns something that differs from 0. (Mostly used with `safemalloc` to find memory leaks)
t	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

Some examples of debug control strings that might appear on a shell command line (the `-#` is typically used to introduce a control string to an application program) are:

```
-#d:t
-#d:f,main,subr1:F:L:t,20
-#d,input,output,files:n
-#d:t:i:O,\\mysqld.trace
```

In MySQL, common tags to print (with the `d` option) are `enter`, `exit`, `error`, `warning`, `info`,

and `loop`.

E.4. Comments about RTS Threads

I have tried to use the RTS thread packages with MySQL but stumbled on the following problems:

They use old versions of many POSIX calls and it is very tedious to make wrappers for all functions. I am inclined to think that it would be easier to change the thread libraries to the newest POSIX specification.

Some wrappers are currently written. See `mysys/my_pthread.c` for more info.

At least the following should be changed:

`pthread_get_specific` should use one argument. `sigwait` should take two arguments. A lot of functions (at least `pthread_cond_wait`, `pthread_cond_timedwait()`) should return the error code on error. Now they return -1 and set `errno`.

Another problem is that user-level threads use the `ALRM` signal and this aborts a lot of functions (`read`, `write`, `open`...). MySQL should do a retry on interrupt on all of these but it is not that easy to verify it.

The biggest unsolved problem is the following:

To get thread-level alarms I changed `mysys/thr_alarm.c` to wait between alarms with `pthread_cond_timedwait()`, but this aborts with error `EINTR`. I tried to debug the thread library as to why this happens, but couldn't find any easy solution.

If someone wants to try MySQL with RTS threads I suggest the following:

- Change functions MySQL uses from the thread library to POSIX. This shouldn't take that long.
- Compile all libraries with the `-DHAVE_rts_threads`.
- Compile `thr_alarm`.
- If there are some small differences in the implementation, they may be fixed by changing `my_pthread.h` and `my_pthread.c`.
- Run `thr_alarm`. If it runs without any “warning,” “error,” or aborted messages, you are on the right track. Here is a successful run on Solaris:

```
Main thread: 1
Thread 0 (5) started

E.5. Differences Between Thread Packages

MySQL is very dependent on the thread package used. So when choosing a good platform for MySQL, the thread package is very important.

There are at least three types of thread packages:

- User threads in a single process. Thread switching is managed with alarms and the threads library manages all non-thread-safe functions with locks. Read, write and select operations are usually managed with a thread-specific select that switches to another thread if the running threads have to wait for data. If the user thread packages are integrated in the standard libs (FreeBSD and BSDI threads) the thread package requires less overhead than thread packages that have to map all unsafe calls (MIT-pthreads, FSU Pthreads and RTS threads). In some environments (for example, SCO), all system calls are thread-safe so the mapping can be done very easily (FSU Pthreads on SCO). Downside: All mapped calls take a little time and it's quite tricky to be able to handle all situations. There are usually also some system calls that are not handled by the thread package (like MIT-pthreads and sockets). Thread scheduling isn't always optimal.

- User threads in separate processes. Thread switching is done by the kernel and all data are shared between threads. The thread package manages the standard thread calls to allow sharing data between threads. LinuxThreads is using this method. Downside: Lots of processes. Thread creating is slow. If one thread dies the rest are usually left hanging and you must kill them all before restarting. Thread switching is somewhat expensive.

- Kernel threads. Thread switching is handled by the thread library or the kernel and is very fast. Everything is done in one process, but on some systems, `ps` may show the different threads. If one thread aborts, the whole process aborts. Most system calls are thread-safe and should require very little overhead. Solaris, HP-UX, AIX and OSF/1 have kernel threads.

In some systems kernel threads are managed by integrating user level threads in the system libraries. In such cases, the thread switching can only be done by the thread library and the kernel isn't really “thread aware.”

Appendix F. Environment Variables

This appendix lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.3.2, “Using Option Files”.

Variable	Description
CXX	The name of your C++ compiler (for running `configure`).
CC	The name of your C compiler (for running `configure`).
CFLAGS	Flags for your C compiler (for running `configure`).
CXXFLAGS	Flags for your C++ compiler (for running `configure`).
DBI_USER	The default username for Perl DBI.
DBI_TRACE	Trace options for Perl DBI.
HOME	The default path for the `mysql` history file is `$HOME/.mysql_history`.
LD_RUN_PATH	Used to specify the location of `libmysqlclient.so`.
MYSQL_DEBUG	Debug trace options when debugging.
MYSQL_HISTFILE	The path to the `mysql` history file. If this variable is set, its value overrides the default for `$HOME/.mysql_history`.
MYSQL_HOST	The default hostname used by the `mysql` command-line client.
MYSQL_PS1	The command prompt to use in the `mysql` command-line client.
MYSQL_PWD	The default password when connecting to `mysqld`. Note that using this is insecure. See Section 5.8.6, “Keeping Your Password Secure”.
MYSQL_TCP_PORT	The default TCP/IP port number.
MYSQL_UNIX_PORT	The default Unix socket filename; used for connections to `localhost`.
PATH	Used by the shell to find MySQL programs.
TMPDIR	The directory where temporary files are created.
TZ	This should be set to your local time zone. See Section A.4.6, “Time Zone Problems”.
UMASK_DIR	The user-directory creation mask when creating directories. Note that this is ANDed with UMASK.
UMASK	The user-file creation mask when creating files.
USER	The default username on Windows and NetWare used when connecting to `mysqld`.

Appendix G. MySQL Regular Expressions

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. See Appendix C, *Credits*. MySQL uses the extended version to support pattern-matching operations performed with the `REGEXP` operator in SQL statements. See Section 3.3.4.7, "Pattern Matching".

This appendix is a summary, with examples, of the special characters and constructs that can be used in MySQL for `REGEXP` operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory.

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Non-trivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`

  Match the beginning of a string.

  ```
  mysql> SELECT 'fo\nfo' REGEXP '^fo$';                    -> 0
  mysql> SELECT 'fofo' REGEXP '^fo';                       -> 1
  ```

- `$`

  Match the end of a string.

  ```
  mysql> SELECT 'fo\no' REGEXP '^fo\no$';                  -> 1
  mysql> SELECT 'fo\no' REGEXP '^fo$';                     -> 0
  ```

- `.`

  Match any character (including carriage return and newline).

  ```
  mysql> SELECT 'fofo' REGEXP '^f.*$';                     -> 1
  mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$';                 -> 1
  ```

- `a*`

  Match any sequence of zero or more `a` characters.

  ```
  mysql> SELECT 'Ban' REGEXP '^Ba*n';                      -> 1
  mysql> SELECT 'Baaan' REGEXP '^Ba*n';                    -> 1
  mysql> SELECT 'Bn' REGEXP '^Ba*n';                       -> 1
  ```

- `a+`

  Match any sequence of one or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba+n';                -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n';                 -> 0
```

- `a?`

  Match either zero or one `a` character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n';                 -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n';                -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n';               -> 0
```

- `de|abc`

  Match either of the sequences `de` or `abc`.

```
mysql> SELECT 'pi' REGEXP 'pi|apa';                -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa';               -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa';               -> 1
mysql> SELECT 'apa' REGEXP '^(pi|apa)$';           -> 1
mysql> SELECT 'pi' REGEXP '^(pi|apa)$';            -> 1
mysql> SELECT 'pix' REGEXP '^(pi|apa)$';           -> 0
```

- `(abc)*`

  Match zero or more instances of the sequence `abc`.

```
mysql> SELECT 'pi' REGEXP '^(pi)*$';               -> 1
mysql> SELECT 'pip' REGEXP '^(pi)*$';              -> 0
mysql> SELECT 'pipi' REGEXP '^(pi)*$';             -> 1
```

- `{1}`, `{2,3}`

  `{n}` or `{m,n}` notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

  - `a*`

    Can be written as `a{0,}`.

  - `a+`

    Can be written as `a{1,}`.

  - `a?`

    Can be written as `a{0,1}`.

  To be more precise, `a{n}` matches exactly `n` instances of `a`. `a{n,}` matches `n` or more instances of `a`. `a{m,n}` matches `m` through `n` instances of `a`, inclusive.

  `m` and `n` must be in the range from `0` to `RE_DUP_MAX` (default 255), inclusive. If both `m` and `n` are given, `m` must be less than or equal to `n`.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e';         -> 0
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e';         -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e';      -> 1
```

- `[a-dX]`, `[^a-dX]`

  Matches any character that is (or is not, if `^` is used) either `a`, `b`, `c`, `d` or `X`. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[]` pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]';                -> 1
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]$';              -> 0
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]+$';             -> 1
mysql> SELECT 'aXbc' REGEXP '^[^a-dXYZ]+$';            -> 0
mysql> SELECT 'gheis' REGEXP '^[^a-dXYZ]+$';           -> 1
mysql> SELECT 'gheisa' REGEXP '^[^a-dXYZ]+$';          -> 0
```

- `[.characters.]`

  Within a bracket expression (written using `[` and `]`), matches the sequence of characters of that collating element. `characters` is either a single character or a character name like `newline`. You can find the full list of character names in the `regexp/cname.h` file.

```
mysql> SELECT '~' REGEXP '[[.~.]]';                    -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';                -> 1
```

- `[=character_class=]`

  Within a bracket expression (written using `[` and `]`), `[=character_class=]` represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if `o` and `(+)` are the members of an equivalence class, then `[[=o=]]`, `[[=(+)=]]`, and `[o(+)]` are all synonymous. An equivalence class may not be used as an endpoint of a range.

- `[:character_class:]`

  Within a bracket expression (written using `[` and `]`), `[:character_class:]` represents a character class that matches all characters belonging to that class. The standard class names are:

`alnum`	Alphanumeric characters
`alpha`	Alphabetic characters
`blank`	Whitespace characters
`cntrl`	Control characters
`digit`	Digit characters
`graph`	Graphic characters
`lower`	Lowercase alphabetic characters
`print`	Graphic or space characters
`punct`	Punctuation characters
`space`	Space, tab, newline, and carriage return
`upper`	Uppercase alphabetic characters
`xdigit`	Hexadecimal digit characters

  These stand for the character classes defined in the `ctype(3)` manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

```
mysql> SELECT 'justalnums' REGEXP '[[:alnum:]]+';       -> 1
```

```
mysql> SELECT '!!' REGEXP '[[:alnum:]]+';                -> 0
```

- `[[:<:]]`, `[[:>:]]`

  These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (_).

  ```
  mysql> SELECT 'a word a' REGEXP '[[:<:]]word[[:>:]]';   -> 1
  mysql> SELECT 'a xword a' REGEXP '[[:<:]]word[[:>:]]';  -> 0
  ```

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2';                         -> 0
mysql> SELECT '1+2' REGEXP '1\+2';                        -> 0
mysql> SELECT '1+2' REGEXP '1\\+2';                       -> 1
```

Appendix H. Limits in MySQL

This Appendix lists current limits in MySQL 5.1.

H.1. Limits of Joins

The maximum number of tables that can be referenced in a single join is 61. This also applies to the number of tables that can be referenced in the definition of a view.

Appendix I. Feature Restrictions

The discussion here describes restrictions that apply to the use of MySQL features such as subqueries or views.

I.1. Restrictions on Stored Routines and Triggers

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. Some of restrictions apply only to stored functions, and not to stored procedures.

All of the restrictions for stored functions also apply to triggers. In addition, triggers currently are not activated by foreign key actions.

Note: If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL interprets the reference as the name of a variable. This is non-standard behavior; the order of precedence is usually column names, then SQL variables and parameters. See Section 20.2.9.3, "`SELECT ... INTO` Statement".

Stored routines cannot contain arbitrary SQL statements. The following statements are disallowed within stored routines:

- The locking statements `LOCK TABLES`, `UNLOCK TABLES`.
- `LOAD DATA` and `LOAD TABLE`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`). Implication: You cannot use dynamic SQL within stored routines (where you construct dynamically statements as strings and then execute them). This restriction is lifted as of MySQL 5.0.13 for stored procedures; it still applies to stored functions and triggers.

For stored functions (but not stored procedures), the following additional statements are disallowed:

- Statements that do explicit or implicit commit or rollback.
- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO` clause and `SHOW` statements. A function can process a result set either with `SELECT ... INTO` or by using a cursor and `FETCH` statements.
- `FLUSH` statements. Note that while you may use `FLUSH` in a stored procedure, such a stored procedure cannot be called from a stored function or trigger.
- Recursive statements. That is, stored functions cannot be used recursively.

Note that although some restrictions normally apply to stored functions and triggers but not to stored procedures, those restrictions do apply to stored procedures if they are invoked from within a stored function or trigger.

It is possible for the same identifier to be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
  BEGIN
    DECLARE i INT DEFAULT 1;
```

```
    SELECT i FROM t;
  END;
END;
```

In such cases the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column
- A routine parameter takes precedence over a table column
- A local variable in an inner block takes precedence over a local variable in an outer block

The behavior that table columns do not take precedence over variable s is non-standard.

Use of stored routines can cause replication problems. This issue is discussed further in Section 20.4, “Binary Logging of Stored Routines and Triggers”.

`INFORMATION_SCHEMA` does not yet have a `PARAMETERS` table, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of `SHOW CREATE` statements.

There are no stored routine debugging facilities.

`CALL` statements cannot be prepared. This true both for server-side prepared statements and for SQL prepared statements.

To prevent problems of interaction between server threads, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. This means that while the statement executes, it will not see changes to routines performed by other threads.

I.2. Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API via the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor allows a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

A server-side cursor is materialized into a temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table if its size reaches the value of the `max_heap_table_size` system variable. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read-only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.

Cursors are non-holdable (not held open after a commit).

Cursors are asensitive.

Cursors are non-scrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLES`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

I.3. Restrictions on Subqueries

Known bug to be fixed later: If you compare a `NULL` value to a subquery using `ALL`, `ANY`, or `SOME`, and the subquery returns an empty result, the comparison might evaluate to the non-standard result of `NULL` rather than to `TRUE` or `FALSE`.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

Row comparison operations are only partially supported:

- For *`expr`* `IN (`*`subquery`*`)`, *`expr`* can be an *n*-tuple (specified via row constructor syntax) and the subquery can return rows of *n*-tuples.
- For *`expr op`* `{ALL|ANY|SOME} (`*`subquery`*`)`, *`expr`* must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of *n*-tuples, this is supported:

```
(val_1, ..., val_n) IN (subquery)
```

But this is not supported:

```
(val_1, ..., val_n) op {ALL|ANY|SOME} (subquery)
```

The reason for supporting row comparisons for `IN` but not for the others is that `IN` was implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

Row constructors are not well optimized. The following two expressions are equivalent, but only the second can be optimized:

```
(col1, col2, ...) = (val1, val2, ...)
col1 = val1 AND col2 = val2 AND ...
```

Subquery optimization for `IN` is not as effective as for `=`.

A typical case for poor `IN` performance is when the subquery returns a small number of rows but the outer query returns a large number of rows to be compared to the subquery result.

Subqueries in the `FROM` clause cannot be correlated subqueries. They are materialized (executed to produce a result set) before evaluating the outer query, so they cannot be evaluated per row of the outer query.

In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if you are using a subquery for the modified table in the `FROM` clause. Example:

```
UPDATE t ... WHERE col = (SELECT (SELECT ... FROM t...) AS _t ...);
```

Here the prohibition does not apply because a subquery in the `FROM` clause is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

The optimizer is more mature for joins than for subqueries, so in many cases a statement that uses a subquery can be executed more efficiently if you rewrite it as a join.

An exception occurs for the case where an `IN` subquery can be rewritten as a `SELECT DISTINCT` join. Example:

```
SELECT col FROM t1 WHERE id_col IN (SELECT id_col2 FROM t2 WHERE condition);
```

That statement can be rewritten as follows:

```
SELECT DISTINCT col FROM t1, t2 WHERE t1.id_col = t2.id_col AND condition;
```

But in this case, the join requires an extra `DISTINCT` operation and is not more efficient than the subquery.

Possible future optimization: MySQL doesn't rewrite the join order for subquery evaluation. In some cases, a subquery could be executed more efficiently if MySQL rewrote it as a join. This would give the optimizer a chance to choose between more execution plans. For example, it can decide whether to read one table or the other first.

Example:

```
SELECT a FROM outer_table AS ot
WHERE a IN (SELECT a FROM inner_table AS it WHERE ot.b = it.b);
```

For that query, MySQL always scans `outer_table` first and then executes the subquery on `inner_table` for each row. If `outer_table` has a lot of rows and `inner_table` has few rows, the query probably will not be as fast as it could be.

The preceding query could be rewritten like this:

```
SELECT a FROM outer_table AS ot, inner_table AS it
WHERE ot.a = it.a AND ot.b = it.b;
```

In this case, we can scan the small table (`inner_table`) and look up rows in `outer_table`, which will be fast if there is an index on `(ot.a,ot.b)`.

Possible future optimization: A correlated subquery is evaluated for each row of the outer query. A better approach is that if the outer row values do not change from the previous row, do not evaluate the subquery again. Instead use its previous result.

Possible future optimization: A subquery in the `FROM` clause is evaluated by materializing the result into a temporary table, and this table does not use indexes. This does not allow the use of indexes in comparison with other tables in the query, although that might be useful.

Possible future optimization: If a subquery in the `FROM` clause resembles a view to which the merge algorithm can be applied, rewrite the query and apply the merge algorithm so that indexes can be used. The following statement contains such a subquery:

```
SELECT * FROM (SELECT * FROM t1 WHERE t1.t1_col) AS _t1, t2 WHERE t2.t2_col;
```

The statement can be rewritten as a join like this:

```
SELECT * FROM t1, t2 WHERE t1.t1_col AND t2.t2_col;
```

This type of rewriting would provide two benefits:

1. It avoids the use of a temporary table for which no indexes can be used. In the rewritten query, the optimizer can use indexes on `t1`.
2. It gives the optimizer more freedom to choose between different execution plans. For example, rewriting the query as a join allows the optimizer to use `t1` or `t2` first.

Possible future optimization: For `IN`, `= ANY`, `<> ANY`, `= ALL`, and `<> ALL` with non-correlated subqueries, use an in-memory hash for a result result or a temporary table with an index for larger results. Example:

```
SELECT a FROM big_table AS bt
WHERE non_key_field IN (SELECT non_key_field FROM table WHERE condition)
```

In this case, we could create a temporary table:

```
CREATE TABLE t (key (non_key_field))
(SELECT non_key_field FROM table WHERE condition)
```

Then, for each row in `big_table`, do a key lookup in `t` based on `bt.non_key_field`.

I.4. Restrictions on Views

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the `FROM` clause of a view. This limitation will be lifted in the future.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section I.3, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);

UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you *can* select from the table in the view subquery and still modify that table in the outer query. In this case the view will be materialized and thus you aren't really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` keyword in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition (which invalidates the view) and no warning results from the drop or alter operation. An error occurs later when the view is used.

A view definition is “frozen” by certain statements:

- If a statement prepared by `PREPARE` refers to a view, the view contents seen each time the statement is executed later will be the contents of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed. Example:

  ```
  CREATE VIEW v AS SELECT 1;
  PREPARE s FROM 'SELECT * FROM v';
  ALTER VIEW v AS SELECT 2;
  EXECUTE s;
  ```

  The result returned by the `EXECUTE` statement is 1, not 2.

- If a statement in a stored routine refers to a view, the view contents seen by the statement are its contents the first time that statement is executed. For example, this means that if the statement is executed in a loop, further iterations of the statement see the same view contents, even if the view definition is changed later in the loop. Example:

  ```
  CREATE VIEW v AS SELECT 1;
  delimiter //
  CREATE PROCEDURE p ()
  BEGIN
    DECLARE i INT DEFAULT 0;
    WHILE i < 5 DO
      SELECT * FROM v;
      SET i = i + 1;
      ALTER VIEW v AS SELECT 2;
    END WHILE;
  END;
  //
  delimiter ;
  CALL p();
  ```

  When the procedure p() is called, the SELECT returns 1 each time through the loop, even though the view definition is changed within the loop.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. This includes views that have `UNION` in their definition. Currently, not all views that are theoretically updatable can be updated. The initial view implementation was deliberately written this way in order to get usable, updatable views into MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist:

- Updatable views with subqueries anywhere other than in the `WHERE` clause. Some views that have subqueries in the `SELECT` list may be updatable.

- You cannot use `UPDATE` to update more than one underlying table of a view that is defined as a join.

- You cannot use `DELETE` to update a view that is defined as a join.

I.5. Restrictions on XA Transactions

XA transaction support is limited to the `InnoDB` storage engine.

The MySQL XA implementation is for `external XA,`, where a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. “Internal XA” is not implemen-

ted. This would allow individual storage engines within a MySQL server to act as RMs, and the server itself to act as a TM. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA is incomplete because it requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for `InnoDB`.

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is not supported.

The requirement that the *`bqual`* part of the *`xid`* value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the `PREPARED` state and the MySQL server dies, the transaction can be continued after the server restarts. That is as it should be. However, if the client connection terminates and the server continues to run, the server rolls back any pending XA transaction, even one that has reached the `PREPARED` state. It should be possible to commit or roll back a `PREPARED` XA transaction, but this cannot be done without changes to the binary logging mechanism.

Appendix J. GNU General Public License

Version 2, June 1991

Copyright © 1989, 1991 Free Software Foundation, Inc.
59 Temple Place - Suite 330, Boston, MA 02111-1307, USA
Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software---to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

1. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The ``Program", below, refers to any such program or work, and a ``work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or trans-

lated into another language. (Hereinafter, translation is included without limitation in the term ``modification".) Each licensee is addressed as ``you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

2. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

   You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

3. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

   a. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

   b. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

   c. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

   These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

   Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

   In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

4. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

   a. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

   b. Accompany it with a written offer, valid for at least three years, to give any third-party,

for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

5. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

6. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

7. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

8. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

   If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

   It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and

a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

9. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

10. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

    Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and ``any later version'', you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

11. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

    NO WARRANTY

12. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM ``AS IS'' WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

13. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each

source file to most effectively convey the exclusion of warranty; and each file should have at least the ``copyright'' line and a pointer to where the full notice is found.

```
one line to give the program's name and a brief idea of what it does.
Copyright (C) yyyy  name of author

This program is free software; you can redistribute it and/or modify
it under the terms of the GNU General Public License as published by
the Free Software Foundation; either version 2 of the License, or
(at your option) any later version.

This program is distributed in the hope that it will be useful,
but WITHOUT ANY WARRANTY; without even the implied warranty of
MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the
GNU General Public License for more details.

You should have received a copy of the GNU General Public License
along with this program; if not, write to the Free Software
Foundation, Inc., 59 Temple Place - Suite 330, Boston, MA  02111-1307, USA.
```

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) 19yy name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands '`show w`' and '`show c`' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than '`show w`' and '`show c`'; they could even be mouse-clicks or menu items---whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a ``copyright disclaimer'' for the program, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the program
`Gnomovision' (which makes passes at compilers) written by James Hacker.

signature of Ty Coon, 1 April 1989
Ty Coon, President of Vice
```

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

Appendix K. MySQL FLOSS License Exception

The MySQL AB Exception for Free/Libre and Open Source Software-only Applications Using MySQL Client Libraries (the “FLOSS Exception”).

Version 0.4, 08 September 2005

Exception Intent

We want specified Free/Libre and Open Source Software (``FLOSS'') applications to be able to use specified GPL-licensed MySQL client libraries (the ``Program'') despite the fact that not all FLOSS licenses are compatible with version 2 of the GNU General Public License (the ``GPL'').

Legal Terms and Conditions

As a special exception to the terms and conditions of version 2.0 of the GPL:

1. You are free to distribute a Derivative Work that is formed entirely from the Program and one or more works (each, a “FLOSS Work”) licensed under one or more of the licenses listed below in section 1, as long as:

   a. You obey the GPL in all respects for the Program and the Derivative Work, except for identifiable sections of the Derivative Work which are not derived from the Program, and which can reasonably be considered independent and separate works in themselves,

   b. all identifiable sections of the Derivative Work which are not derived from the Program, and which can reasonably be considered independent and separate works in themselves,

      i. are distributed subject to one of the FLOSS licenses listed below, and

      ii. the object code or executable form of those sections are accompanied by the complete corresponding machine-readable source code for those sections on the same medium and under the same FLOSS license as the corresponding object code or executable forms of those sections, and

   c. any works which are aggregated with the Program or with a Derivative Work on a volume of a storage or distribution medium in accordance with the GPL, can reasonably be considered independent and separate works in themselves which are not derivatives of either the Program, a Derivative Work or a FLOSS Work.

   If the above conditions are not met, then the Program may only be copied, modified, distributed or used under the terms and conditions of the GPL or another valid licensing option from MySQL AB.

2. **FLOSS License List**

License name	Version(s)/Copyright Date
Academic Free License	2.0
Apache Software License	1.0/1.1/2.0
Apple Public Source License	2.0
Artistic license	From Perl 5.8.0
BSD license	"July 22 1999"
Common Public License	1.0
GNU Library or "Lesser" General Public License (LGPL)	2.0/2.1
Jabber Open Source License	1.0

MIT license	-
Mozilla Public License (MPL)	1.0/1.1
Open Software License	2.0
OpenSSL license (with original SSLeay license)	"2003" ("1998")
PHP License	3.0
Python license (CNRI Python License)	—
Python Software Foundation License	2.1.1
Sleepycat License	"1999"
W3C License	"2001"
X11 License	"2001"
Zlib/libpng License	—
Zope Public License	2.0

Due to the many variants of some of the above licenses, we require that any version follow the 2003 version of the Free Software Foundation's Free Software Definition (http://www.gnu.org/philosophy/free-sw.html) or version 1.9 of the Open Source Definition by the Open Source Initiative (http://www.opensource.org/docs/definition.php).

3. Definitions

   a. Terms used, but not defined, herein shall have the meaning provided in the GPL.

   b. Derivative Work means a derivative work under copyright law.

4. **Applicability**: This FLOSS Exception applies to all Programs that contain a notice placed by MySQL AB saying that the Program may be distributed under the terms of this FLOSS Exception. If you create or distribute a work which is a Derivative Work of both the Program and any other work licensed under the GPL, then this FLOSS Exception is not available for that work; thus, you must remove the FLOSS Exception notice from that work and comply with the GPL in all respects, including by retaining all GPL notices. You may choose to redistribute a copy of the Program exclusively under the terms of the GPL by removing the FLOSS Exception notice from that copy of the Program, provided that the copy has never been modified by you or any third party.

Appendix A. Qualified Libraries and Packages

The following is a non-exhaustive list of libraries and packages which are covered by the FLOSS License Exception. Please note that this appendix is provided merely as an additional service to specific FLOSS projects wishing to simplify licensing information for their users. Compliance with one of the licenses noted under the “FLOSS license list” section remains a prerequisite.

Package Name	**Qualifying License and Version**
Apache Portable Runtime (APR)	Apache Software License 2.0
